3015. Taking the next year, 1864, it appears that there were only eight days in which the volume of water was below 400,000,000 gallons?—Yes; and five out of those eight are in January; that arose from severe frost; on two occasions in the year 1855, during the very severe frost, the volume of water flowing past Kingston was reduced to nearly 350,000,000 gallons.

3016. (*Mr Prestwich*) Have you given the mean delivery of the driest year—not any particular day—but dividing the year by the number of days and taking the mean of that year?—In the year 1857–8 the total discharge at Kingston was 402,034,000,000 gallons; that divided by 365 gives about as an average 1,100,000,000 gallons. The smallest average discharge was in 1858–9, being just 800,000,000 gallons per day.

3017. (*Mr. Harrison.*) It is stated at the bottom of Table No. 3, "The average daily discharge at Kings-"ton between April 1858 and April 1859," (which is the least discharge) "was 800,000,000 gallons per "day"?—Yes.

3018. And the average daily discharge in 1864, which was the next driest year, was just 1,000,000,000 gallons daily?—Yes.

3019. There appears to be an anomaly in this table which perhaps you may be able to explain; it appears that in the year 1857–58 the rainfall was 1,214,814,000,000, and the discharge at Kingston was 402,034,000,000 gallons; taking the next year the rainfall was 1,313,024,000,000 being in excess by nearly 100,000,000,000 gallons of the rainfall of the previous year; but the discharge at Kingston in that year appears to have been only 293,143,000,000; therefore there is a larger rainfall in 1858 than there is in 1857, but a larger discharge at Kingston in 1857 than there is in 1858?—Yes; I have no doubt that the diagram which I have handed in will explain it in a moment. You will observe that previous to April 1857 there was a considerable rainfall and a pretty full river (supplied chiefly from springs) throughout the summer; during the winter there was comparatively little extra discharge and a small rainfall, the rainfall which appears so large in the year 1858 occurred chiefly during the summer months, when the evaporation in such a year as that would be almost equal to the rainfall, and hardly a drop of the rainfall would find its way to the river.

3020. (*Mr. Prestwich.*) Have you not the gaugings of the different tributaries?—No, we had not the means of obtaining them. I do not think that they exist.

3021. (*Col. Harness.*) At the Colne you have got them, have you not?—No.

3022. Had not Mr. Simpson?—No; he only kept his observations for the purposes of the Chelsea and Lambeth Water Companies, to know what the volume of water passing down the Thames at Kingston was.

3023. Had not Mr. Evans?—No; he is at King's Langley, and he does not care at all what quantity goes into the river below him.

3024. (*Mr. Prestwich.*) The delivery of the different tributaries would vary, would it not, according to their soil?—No doubt. The value of this information I think is indicative of what it is desirable to obtain. If observations were made carefully at certain points in the river and its tributaries, the information would be valuable; such observations as those given by Mr. Simpson could scarcely be obtained respecting any other river. The only approximation to such information we obtained from Mr. Gott, borough surveyor of Bradford. Mr. Gott gave us the daily gauging of the flow of water from Many-Springs, which had been kept during the same period, from 1855 to 1866, and the rainfall in the immediate neighbourhood. He could not give us the area from which the spring water was collected as it was uncertain. But the similarity between the discharge from the springs at Bradford and of the Thames at Kingston is remarkable. This height (*pointing to the diagram*) shows the discharge from a spring at Bradford in Yorkshire simultaneously

T. T. Harrison, Esq.

9 May 1867.

with the discharge from the Thames at Kingston, and the diagrams correspond in a number of cases in a remarkable manner. Such a similarity at two points so far apart could hardly be expected.

3025. (*Mr. Harrison.*) Of course there are particular months in the year when we generally expect a rainfall?—Yes; this correspondence shows that the rainfall which soaks into the ground and comes out in springs is much more similar in different parts of the country than is generally imagined.

3026. (*Mr. Prestwich.*) In Table No. 3 you have divided the rainfall, the discharge at Kingston, and the evaporation, and then you have given the quantity added to or drawn from subterranean reservoirs; that, I presume, marks rather the quantity delivered by springs, independent of immediate rainfall on any particular day or month?—I think you will find what you want in the next table; it marks the difference. There is a certain amount of rainfall, there is a certain volume discharged at Kingston, and there is a certain quantity of water evaporated, and the plus or minus is the difference between the discharge and the evaporation added together and the rainfall.

3027. Then the two first columns give the positive quantities, and the third one is a hypothetical quantity?—The third one is not altogether hypothetical, it is drawn from observations within the Thames basin with a similar rainfall, or nearly so.

3028. Then in fact the quantity derived from the reservoirs would rather indicate that, notwithstanding a moderate rainfall, the quantity delivered from springs in the chalk would be added to that rainfall, and would maintain a greater uniformity of discharge than would otherwise happen?—There is not a doubt about it in some cases. Where there is a considerable plus quantity the reservoirs are comparatively full; the subterranean reservoir is exactly similar in character to an ordinary reservoir more or less full. If there is a surplus quantity it might be delivering 1,000,000,000 gallons per day, at another period when very heavily drawn upon, the subterranean reservoir might be only delivering 500,000,000 gallons per day, a comparison of the table with the diagram shows a remarkable coincidence. I will now hand in Table No. 4.

The witness delivered in the following table:

No. 4.

TABLE showing approximately the VARIATIONS in the VOLUME of WATER in the SUBTERRANEAN RESERVOIRS at the Termination of each Half Year, supposing there were 1,000,000 million gallons on April 1st, 1855:—

	Million Gallons. +	Million Gallons. −	Million Gallons.	Remarks.
1855, April 1	—	—	1,000,000	Heavy continuous rain in July for several weeks.
„ October 1	25,740	—	1,025,740	Do. in October.
1856, April 1	67,268	—	1,093,008	Heavy rain in May, August, and September.
„ October 1	29,232	—	1,132,240	Moderate winter rain.
1857, April 1	—	30,219	1,102,021	Steady summer rain.
„ October 1	—	148,978	953,043	Heavy rain in October, AFTERWARDS DRY WINTER.
1858, April 1	—	44,123	908,920	Do. in April. Steady summer rain.
„ October 1	72,198	—	981,118	Dry winter.
1859, April 1	—	108,359	872,759	June and September heavy rain.
„ October 1	—	77,721	795,038	Abundant winter rain.
1860, April 1	120,682	—	915,720	Very heavy summer rain.
„ October 1	80,585	—	996,305	Considerable winter rain, large quantity passed off in floods.
1861, April 1	—	87,018	909,287	
„ October 1	—	71,848	837,439	Very heavy and steady summer rain.
1862, April 1	163,023	—	1,000,462	Abundant winter rain.
„ October 1	—	92,682	907,780	Steady summer rain.
1863, April 1	—	15,490	892,290	Rain heavy October and January.
„ October 1	—	69,138	823,152	Heavy rain May and September.
1864, April 1	172,444	—	995,596	Do. October and March.
„ October 1	—	63,190	932,406	Very dry summer.
1865, April 1	50,009	—	982,415	Wet November and January.
„ October 1	—	9,360	973,055	Considerable rainfall May to August.
1866, April 1	186,296	—	1,159,351	Extremely wet winter.
	977,477	818,126		
	159,351			

3029. (*Chairman.*) Will you have the goodness to explain that table?—No. 4 is taken from Table No. 3, and shows in the third column what would probably be the condition of the storage in the subterranean reservoirs at the termination of each half-yearly period. There are also some observations opposite to each half year as to the rainfall during the half year.

3030. (*Mr. Harrison.*) You begin with the assumption that you have 1,000,000,000,000 gallons in storage on the 1st of April 1855?—Yes.

3031. And taking it from those preceding tables this would give you the plus or minus that quantity on the 1st of April and the 1st of October every year?—Yes.

3032. And with a note appended to it of the particular circumstances which may have influenced the plus or minus?—Yes.

3033. You also stated here in the year 1855 "heavy "continuous rains in July for several weeks," and "ditto in October;" and in 1856 "heavy rain in May, August, and September," the result of that being that there is a plus in each of those three years?—Yes.

3034. And the next being "moderate winter rain" brings a minus quantity, and then a "steady summer rain," also brings a minus quantity?—Yes, you may have a very heavy summer rain and really add very little indeed to the subterranean supply. The records both of Mr. Greaves and of Mr. Evans show that very frequently for a whole month none of the rainfall percolates through the subsoil to the lower stratum.

3035. (*Col. Harness.*) How do you get at the assumption of 1,000,000,000,000?—It is merely like the base line for a section. It is merely a quantity from or to which you may subtract or add. I will now hand in Table No. 5.

The witness handed in the following table:

No. 5.

THAMES RANIFALL and DISCHARGE.

	Inches.
Rainfall on Thames basin from 1st April 1855 to April 1st, 1866 (average between Kingston and Cirencester)	304·18
Or an annual average of	27·65

(*Note.*) The rainfall at Cirencester averages about 4·4 inches more than at Kingston.

There are three days on which rain falls at Kingston for two days at Cirencester.

The rainfall at Cirencester varied from - - 24·68 to 36·96 in 11 years.
The rainfall at Kingston varied from - - - 19·09 to 32·14 „

1 inch of rain over the Thames basin (area 102,480,000,000 square feet) gives 53,375 million gallons of water.

	Million Gallons.
Volume of water from rainfall over the Thames basin from April 1855 to April 1866 -	16,285,978
Volume of water discharged by Thames, calculated from Mr. James Simpson's data -	5,432,438
Difference - - - -	10,853,540
The daily volume discharged April 1855 was 500 million gallons, and April 1866 1,000 million gallons per day. If no rain fell it would take 150 days for the Thames discharge to fall from 1,000 million gallons to 500 million gallons per day. There was therefore a store in the subterranean reservoirs of at least 750 million gallons × 150 days in April 1866 in excess of April 1855, -	112,500
Leaving evaporated, &c. - -	10,741,040
The volume evaporated from the Thames area, were it all chalk, would according to Mr. Evans' percolation observations be about -	9,859,000
Leaving - - - -	882,040

The extra evaporation from the clay surface of the Thames basin would fully account for this.

3036. (*Chairman.*) What is the object of Tables No. 5?—It brings under view some of the results derivable from the tables which I have already given. I will also hand in Table No. 6.

J. T. Harrison, Esq.

9 May 1867.

The witness delivered in the following table:

No. 6.

DISPOSAL of THAMES RAINFALL, April 1855 to April 1866.

	Million Gallons
Evaporation, &c. - - - -	10,694,209
Discharged { In floods - - -	2,665,818
Discharged { From springs - - -	2,766,600
Reserve in subterranean reservoirs, April 1866 in excess of April 1855 - - -	159,351
Rainfall - - - -	16,285,978

PROPORTIONS.

Evaporated - -	2/3		= 66 per cent.
Passed off from springs - -	1/6	1/3 discharged	= 17 „
Passed off in floods -	1/6		= 17 „

EVAPORATION.

10,694,209 million gallons evaporated in 11 years, 972,200 gallons per annum, or an average of 18·21 inches per annum, varying from 15 inches in 1861 to 22 inches in 1865–6.

3037. (*Mr. Harrison.*) This table, No. 6, professes to give the disposal of the Thames rainfall from April 1855, to April 1856, and is not this the effect of that table, that the evaporation is 10,694,209,000,000 gallons?—Yes, during the whole period.

3038. Discharged in floods, 2,665,818,000,000 gallons, and from springs, 2,766,600,000,000 gallons?—Yes, I should like to explain how those are divided. On diagram No. 1 a line was drawn representing the discharge from springs, all above that line was considered as being discharged from the surface as flood water. Very nearly half the water passed off in the form of flood-water from the surface, and the other half in the whole 11 years appears to have been derived from springs.

3039. The result arrived at from this table, No. 6, appears to be that two-thirds of the rainfall was evaporated, that one-sixth passed off in floods, and one-sixth was discharged from springs?—Yes, two-thirds evaporated and one-third discharged.

3040. (*Col. Harness.*) You would not apply that evaporation of two-thirds, would you, to a place where the rainfall was very much larger?—Certainly not; each district requires to be considered specially. In the mountainous districts of Wales and Cumberland, the rainfall is so much larger, the surface contours, and subsoils (granite, clay, slate, &c.) so different, that I have very little doubt that the evaporation is actually less in inches of depth of rainfall. There you have less pervious stratification, frequently bare and generally very steep, so that the water falling upon it passes rapidly away, and there is very little water left to be evaporated. Besides in such districts the atmosphere is much more humid, so that there is less evaporation. I have no doubt that the evaporation from a mountainous district is much less in actual inches than it is in a district such as the Thames; and as there is a greater rainfall in Wales and Cumberland, the proportion is much larger between the total rainfall and the evaporation.

3041. (*Chairman.*) What is Table No. 7?—Table No. 7 shows the area in square miles of the several geological strata which occupy the surface of the basin of the Thames and its tributaries above Kingston.

The witness delivered in the following table:

No. 7.

TABLE showing the AREA in Square Miles of the several GEOLOGICAL STRATA which occupy the Surface of the BASIN of the THAMES and its TRIBUTARIES above Kingston.

Name of Tributary.	Thames gravel.	Bagshot Sand. Upper.	Bagshot Sand. Middle.	Bagshot Sand. Lower.	London clay.	Plastic clay.	Chalk.	Upper greensand.	Gault.	Lower greensand.	Wealden clay. Chalk	1,047¾	
Wey upper green sand	126	
Great & inferior oolites	327	

TOTALS.

	sq. miles.		sq. feet.
Impervious strata	1,233½	=	34,388,006,400
PERMEABLE			
Shallow	730½	=	20,358,201,600
Deep	1,712¾	=	47,734,790,400
	3,676	=	102,480,998,400

NOTE.—The areas of the impervious and permeable strata of the Plastic clay formation are corrected in the above table as suggested by Mr. Prestwich.

3042. (*Mr. Harrison.*) This table is divided in the first place into the Thames gravel, the Bagshot sand in three deposits, the London clay, the plastic clay, the chalk, the upper greensand, the gault, the lower greensand, &c., in fact it gives the whole of the different sections resulting in a total of 3,676 square miles above Kingston?—Yes.

3043. The area appears to have been divided by you again into impervious strata containing 1,293½ square miles, consisting of London clay, plastic clay, gault, Wealden clay, Kimmeridge clay, Oxford clay, fuller's earth, and lias?—Yes, probably Mr. Prestwich will correct me in putting plastic clay as being all impervious; I believe it is not quite so, I remember from reading his work he shows that it is not so, but still the area of the plastic clay is inconsiderable, 116½ square miles, and a large portion of it is impervious. I could not eliminate it, and therefore I put it all as impervious.

3044. Then the permeable strata are divided into that which is shallow and that which is deep, making the shallow 670¼ square miles, and the deep 1,712 square miles, the total result being impervious strata 1,293½ square miles, and the permeable shallow 670¼ square miles, deep 1,712 square miles?—Yes. The object in dividing it into deep and shallow, I may mention is this: there are large masses of chalk adjoining the Thames (which is an outlet for the springs for a considerable distance,) rising 500 or 600 feet above Ordnance datum, and 400 feet above the Thames itself, which give out water with great regularity. One of the facts mentioned by Mr. Evans is that he found water passing through the chalk descended about six feet per day. When rain falls upon the surface, a large portion of it evaporates, and the remainder passes into the subsoil; but it takes a long time before it passes from the surface to the subterranean reservoir, which extends many miles away from the point of discharge. Thus a considerable time elapses before it reaches the Thames where it is discharged, and the result is a much more steady and continuous flow from those deeply seated springs than from the shallower springs in the oolite district.

3045. (*Mr. Prestwich.*) That is to say, in the chalk district it takes several months before the rainfall is delivered into the shape of springs?—Exactly so.

3046. I see that in your table you have taken the Thames gravel as representing an area of 154 square

miles, is that taken from the Ordnance Survey?—Yes.

3047. Have you subtracted that from the area where that gravel covers either the London clay or the Bagshot sands?—Yes, I have taken it *per se*.

3048. I think that on the Ordnance map the gravel covering the Bagshot sands is not represented?—No doubt there is a considerable area of the Thames basin which is covered with gravel besides that which is mentioned here; but I had not the means of estimating it. A good deal of the London clay and of the Bagshot sands also is covered. I thought it was of importance to test the accuracy of Mr. Clutterbuck's views as to the rise of the water in the chalk from the Thames or any other point where it finds egress, and with that object I went from Reading to Nettlebed, about 8½ miles from Reading, and took the heights of several wells with the aneroid and measured the depths to the water. This section (*producing the same—see Appendix A, E*), shows the result, the surface of the ground, and the depth to the water in the wells at Nettlebed, Highmore Hill, Kidmore End and Caversham are plotted on it, and they give as the general result, that below the line coloured blue on the section the chalk is saturated with water.

3049. How many feet per mile of rise does it give?—It gives a rise on the average of 20 feet per mile. In the lower part it was about 7 feet per mile, and in the upper part about 37 feet per mile. That confirms generally Mr. Clutterbuck's view. We know that the Thames water is very hard, and we know that it obtains much of its hardness by passing through the chalk; the chalk, as the water passes through it, must year by year become more porous as the carbonate of lime is taken away from it; the chalk adjoining the Thames at Caversham near Reading (*pointing to the map*), through which all the water issuing at that point has to pass, must be more porous than the chalk in the neighbourhood of Nettlebed, eight miles distant, through which only the water falling upon the surface above it passes. The chalk at Nettlebed, would consequently be able to hold the water at a higher level, and it might be expected that the line of saturation should under those circumstances rise at a higher gradient as you receded from the Thames than it would in the neighbourhood of the Thames. That struck me as being a philosophical conclusion, and observations appeared to confirm it.

3050. That might arise, might it not, from several causes, from the larger size of the fissures through which the water would be discharged owing to the length of the valley, and again also from the lower chalk at Nettlebed being denser?—Yes; however, that is a subject that wants investigation, and which would well repay further observation.

3051. It shows how large the reservoir held in the chalk is for a gradual delivery into the Thames?—Yes.

3052. And it shows how important to the uniform discharge of the river it is to have a large formation of permeable strata, such as chalk, for the constant supply of the springs?—Yes, the level of the water at Nettlebed above the Thames is 300 feet, and you have in fact a kind of inverted reservoir with water 300 feet deep eight miles from the Thames.

3053. The delivery of which would continue until it was reduced to such a level as that the resistance of the strata would cause the flow to cease throughout a continued period of dry weather?—Yes, when the gravity of the water and the capillary attraction of the chalk in which it is held are equal, there would be a cessation of the flow, but it does not appear even when there is no rain for 240 days after a heavy rainfall, that this limit is nearly attained; the discharge then becomes almost uniform; so that it would probably be a long time before it was very much below 350,000,000 gallons per day. I may state that in making observations on the flow of the Thames between Wallingford and Maidenhead, where the Thames passes over chalk for a considerable distance, I found that there was an accession of water amounting to about 80,000,000 gallons per day insensibly coming into the river through its bed.

3054. Therefore, you consider such an area as that very important as maintaining the uniform flow of the Thames?—Undoubtedly.

3055. As rendering it very independent of the immediate rainfall of any particular month?—Undoubtedly; and much more important with regard to the uniform flow of the Thames than the oolitic district, which is generally shallow. The discharge from the oolite springs is rapid, and comparatively much larger during the winter months in consequence of their shallowness than those from the chalk, and much less during the summer months. The Thames, when I gauged it in September 1865, discharged only about 10,500,000 gallons from the oolitic district, whereas the discharge from the chalk below was 80,000,000 gallons per day directly into the bed of the Thames.

3056. You mean from the chalk between Wallingford and Reading?—Between Wallingford and Maidenhead.

3057. And delivered into the Thames by springs along the banks of the Thames and not by any rivers?—Just so.

3058. Do you think it would be possible to intercept those springs as they flow into the Thames from the body of the chalk?—I think it quite possible by driving into the chalk for some miles at a lower level than the subterranean reservoirs you would get a great deal of water and you might have the discharge from that source under control. In fact the system is adopted to some extent now upon the river Lea. The New River Company pump a large volume of water from wells, and the volume they so pump is largest in quantity when the river is lowest and they thus have recourse to the residuum which would not flow into the river in very dry seasons. I think it would be quite possible in the same manner to tap the chalk reservoir and keep the discharge under control, simply drawing upon it when required.

3059. (*Mr. Harrison.*) Making use of it as a natural reservoir?—Yes.

3060. (*Mr. Prestwich.*) Have you any measure of the springs from the Bagshot sands?—No; I am sorry to say I know very little, excepting from your work upon the subject.

3061. Amongst the shallow permeable strata I see you include a large portion of the oolite, you include the Coral rag and the Portland stone?—Yes. In the upper Thames the strata are very much dislocated, so that in hardly any case is there a large mass of the great oolite rising to a great height above the springs.

3062. By "shallow" you do not mean the absolute depth in feet, but you refer to the rapid delivery of the water that falls upon it?—Yes, it is tantamount to that.

3063. You would refer the permanent supply of perennial springs to the deeper permeable strata, such as the chalk, the upper greensand in the west of the greensand district?—Yes.

3064. With regard to the great and inferior oolites and the Bagshot sands, to which of them should you attach most importance?—Undoubtedly to the chalk. I believe that the chalk is the great source of the steady supply of the Thames. I will now beg leave to hand in Table No. 8.

The witness delivered in the following table:

T. Harrison, Esq.

9 May 1867.

No. 8.

GEOLOGY of THAMES BASIN above WATER COMPANIES WORKS at KINGSTON.

			Permeable strata.	Impervious strata.	Totals.
			Sq. miles.	Sq. miles.	Sq. miles.
	Oolite Division.				
The water from this division is conveyed to the Thames by the Churn, Colne, Leach, Windrush, Evenlode, and Cherwell.	Marlstone - - 84 sq. miles Great and inferior oolite 327 „ Forest marble - - 85½ „ Cornbrash - - 67¾ „	Permeable strata -	564¼	—	751
	Upper and lower lias - 170 „ Fuller's earth - - 16¾ „	Impervious -	—	186¾	
	Oxford Clay Division.				
The water from this division is collected by the Ray, Cole, Ock, and Thame; all of these receive some water from the outcrop of the chalk.	Coral rag - - 103 sq. miles Portland stone - - 29 „ Lower greensand - 24¾ „	Permeable strata -	156¾	—	726¾
	Oxford clay - - 307½ „ Kimmeridge clay - 132¾ „ Gault - - 129¾ „	Impervious -	—	570	
	Chalk Division.				
Almost all the chalk water is gathered by the Thames, Kennet, and Colne.	Chalk - - - - -	Permeable -	907	—	907
	Hastings and Bagshot Sands and London Clay Division.				
The water from this division is brought to the Thames by the London (Whitewater, Blackwater), Wey, Mole (which is sometimes nearly dry).	Tunbridge sands - 17¾ sq. miles Lower Greensand - 27¾ „ Upper Greensand - 202¾ „ Chalk - - - 140¾ „ Plastic clay - - 60 „ Bagshot sands - - 211½ „ Thames gravel - - 154 „ Wealden clay - - 105 „	Permeable -	814½	—	1,291¼
	Gault - - - 22¾ „ Plastic clay - - 56½ „ London clay - - 292½ „	Impervious -	—	503¾	
	Permeable strata - - -		2,442½	—	3,676
	Impervious strata - - -		—	1,233½	

3065. (*Chairman.*) Table No. 8 is a continuation of the previous sheet, is it not?—Yes. If you will be kind enough to look at the map of the Thames basin you will perceive that the strata run very nearly parallel. The part coloured yellow is the Oxford clay; over the whole of the area occupied by the Oxford, Kimmeridge, and Gault clays there is really very little supply from perennial springs. The Thames, which discharges at Dorchester I found in 1865 all but dry; it is sometimes very much flooded indeed, but in dry weather it hardly discharges any water. The upper district is oolitic, the middle district is the chalk, with the Thames winding through it for a very considerable distance. The Thames basin is divided in the last table into these four divisions; the Oolite, the Oxford clay, the Chalk, and the Bagshot sands and London clay. Opposite to each division are placed the tributaries which drain them.

3066. (*Mr. Prestwich.*) Where you are speaking of the drainage area of the Thames do you include all the tributaries of the Thames as low as Kingston?—Yes, all that discharge above the point from which the water companies take their water.

3067. Including the Wealden area as well as the Thames gravel proper?—Yes.

3068. It has been mentioned in evidence by one of the witnesses that if wells were sunk in any of the chalk valleys, such wells must rob the streams of a certain quantity of water, but that would necessarily be the case in whatever way the water was taken, whether taken from wells or from drainage area?—Yes, certainly, you might rob the wells with impunity during a very dry season without very much diminishing the existing flow into the river if the wells were sufficiently distant from the river. It would have the effect of generalising the withdrawal from the subterranean reservoirs throughout the whole year, the discharge would not be so large during the winter months in consequence of the deficiency of water in the subterranean reservoir, and this deficiency would be restored by the winter rain.

3069. It would only be a question of whether the water was taken after passing into the subsoil and delivered by springs, or taken directly it fell upon the surface?—Merely so, so far as the effect upon the rivers.

3070. That is to say, if the water was taken in drainage areas as at Manchester it would only be taken directly at the source instead of passing through permeable strata and through chalk, and delivered in springs the result would be the same?—Yes.

3071. (*Chairman.*) You are desirous, are you not, to call the attention of the Committee to some evidence which was given by Mr. Beardmore before the Pollution of Rivers Commission with reference to the rainfall?—I think that is almost embodied in the tables. Mr. Beardmore stated in evidence that the minimum discharge in 1858 in the river Lee during that very dry season was 18,657,000 gallons per day, and that the New River Company took about 18,000,000 gallons a day; this gives a total minimum flow of about 36,657,000 gallons per day; and he gave us evidence, also, that in September 1865 the flow altogether, the New River and the Lea, at Kingsweir was 4,550 cubic feet per minute, or 40,550,000 gallons. The discharge from the Thames calculated in proportion to their respective areas would give a minimum about 370,000,000 gallons of water per day.

3072. Has your attention been directed to the mode of distributing water in towns, especially in the metropolis?—We have had evidence upon that point both from Mr. Muir, the engineer of the New River Company, and from Mr. Greaves, the engineer of the East London Company; Mr. Muir stated to us in the evidence which I have laid before the Commission at question 1221, that in some model lodging houses

only seven gallons per head per day were used with virtually a constant supply of water, as the consumers had a large cistern which was never emptied.

3073. His answer is, "From experiments which I "made some years ago in model lodging houses I "found that their actual requirements, allowing them "to take as much as they required, did not amount "to more than seven gallons per head per day, but "rather less; a great deal more than that is allowed "them?"—Yes, that is his answer. Again, if you look at question 1231, you will see that he considers the supply might be reduced to 15 gallons per head throughout the district if proper provision were made to prevent waste.

3074. (*Mr. Prestwich.*) Was that including all purposes?—No, I assume that that was for domestic supply. At question 1183 Mr. Muir gives us this evidence, that his company supply 112,000 houses, and at question 1189 he says, that the population is about 7½ persons per house, that gives a population of 840,000.

3075. He says, I think, that the average of the whole of the metropolis is 8½ persons per house?—Yes, but in their district it is 7½, it is rather a better district than some others in that respect. At question 1198 he gives as the quantity of water used for trade purposes 2,300,000 gallons per day on an average, the total supply being 22,500,000 gallons, there are left for domestic purposes 20,200,000 gallons per day, giving 24 gallons per head per day as the supply for all except trade purposes, so that the reduction to 15 gallons would be from 24 gallons per head. But if you look at questions 3095 and 3096 he puts the consumption at 30 gallons per head, and he states that the difference between that and the 7 gallons per head, which he finds sufficient in the case of the model lodging houses, is wasted through defective ballcocks and other apparatus.

3076. (*Chairman.*) I presume that he means through the apparatus being defective or being tampered with?—Yes; then at question 1231 you will observe he says that he does not consider it would be any disadvantage to the New River Company if they were obliged to afford a constant supply, and that the quantity per head might be reduced to about 15 gallons if they had proper means to prevent waste. The evidence of Mr. Greaves, the Engineer of the East London Company, is very nearly to the same effect. At question 295 he gives the number of houses as 90,000, and at question 1019 he gives eight persons per house as the average. That gives the population supplied by the East London Water Company as about 720,000; at question 193 he gives 20,000,000 gallons as the volume delivered, that would be 28 gallons per head for all purposes. In the appendix to his evidence, you will see it mentioned that for trade purposes they supply 5,000,000 gallons per day, which reduces the supply for domestic purposes to 15,000,000 gallons per day, or 21 gallons per head. He states at questions from 1016 to 1020 that there are very large districts that do not take more than from 60 to 120 gallons per house per day, which with an average of eight persons per house works out to about 8 to 15 gallons per head; and he says at question 1017 that a constant supply would not be more distressing to the water company than an intermittent supply, if proper power were given to them to look after the consumption. I may mention that we found at Bradford in Yorkshire the supply per head was 15 or 16 gallons, and in some towns it was 12 gallons per head for domestic purposes, with no restriction put upon the quantity used.

3077. What was the average consumption per head?—15 or 16 gallons. At Halifax, with a population of 92,000, the quantity per head was 12 or 13 gallons for domestic purposes. At Leeds, for domestic supply which is constant, and watering the streets, the quantity is 16 gallons per head.

3078. (*Mr. Prestwich.*) From those facts have you formed any opinion as to what would be a sufficient supply per head in London?—The evidence that we have received appears to point distinctly to about 15 or 16 gallons per head, being an ample supply for domestic purposes, including waterclosets and watering streets.

3079. What per-centage would you add for trade purposes?—That varies in every town.

3080. What would it be, speaking of London?—I cannot say. I presume that the East London Water Company supply as much in proportion as any company for trade purposes. In Bradford and some of the towns in Yorkshire the first object is a good supply for manufacturing purposes, the supply for domestic purposes is a secondary object.

3081. (*Chairman.*) Do you think that 25 gallons per head would be sufficient both for domestic and trade purposes?—I am not prepared to say that. According to the information received from the east of London, taking that as a guide, that would be more than sufficient.

3082. (*Mr. Prestwich*). Would not the wants of the east of London be more than the average trade requirements of the metropolis?—There is no doubt about it.

3083. (*Mr. Harrison.*) In large houses, taking the west end of London, where baths are used extensively, and where perhaps there are many circumstances that cause a large consumption of water, you find that the consumption per head is a good deal more than that, do you not?—On our inquiry on the Aire and Calder, Mr. Filliter, of Leeds, gave us information as to the quantity of water that he himself consumed in his house with a family of 10. He said that he used 300 gallons per day—that is 30 gallons per head; he had taken the quantity by meter and had carefully examined it. He went into a detail of the mode in which this was consumed, and it appeared that he had two baths, one holding about 70 gallons, and the other about 80 gallons, one he filled twice a day and the other once a day. Consequently 230 out of 300 gallons were used in the baths, the remaining 70 being sufficient for all other purposes, or 7 gallons per head upon his family of 10. That instance shows the enormous consumption there may be in the use of baths.

3084. (*Mr. Harrison.*) The present quantity of water taken from the Thames above Teddington Lock is about 60,000,000 gallons a day, is it not?—Mr. Simpson mentioned last spring that 60,000,000 was the largest quantity that had ever been taken up to that date; in December last the quantity taken was 48,000,000, and 42,000,000 gallons were taken from the Lea.

3085. Have not the companies the power under their existing Acts of taking 50,000,000 gallons more than that?—They have the power of taking 100,000,000 gallons altogether.

3086. It would appear from the information which you have given us, that taking the driest year there have been only 36 days in which the supply passing Teddington Lock, or passing Kingston has fallen below 400,000,000 gallons a day?—Yes, that is the only case during 11 years.

3087. In the year 1858 there were 36 days; in the year 1859 32 days, and in the year 1864 eight days?—Yes, five of those eight being during severe frost.

3088. Then during the remainder of the 11 years there does not appear to have been any period in which it has fallen to so low an amount as 400,000,000 gallons a day?—I can hardly say that, but those are the most striking periods.

3089. Assuming that a larger quantity were taken from the Thames above Teddington Lock, the only injurious effect of that would be between Teddington Lock and, perhaps, Putney, or the point to which at neap tides the tide will flow?—Yes, from the evidence we have it affects the Thames to some extent between Teddington Lock and Putney; above Teddington Lock the water may be kept up to a considerable height by boards.

J. T. Harrison, Esq.

9 May 1867.

3090. It would merely affect the question as regards the navigation practically between Putney and Teddington Lock?—Yes, that portion of the river is now navigable only with the tide; at low water it is not navigable.

3091. Has your attention at all been given to any serious effect which the abstracting of so large a quantity of water would have upon the Thames below Teddington, has that formed a portion of your investigation?—Captain Burstal informed us that the volume of water going down would have no effect upon the sands lying at the mouth of the Thames; and he said that the shoals through London dredged of late years were found to be to a very great extent clay, and not sand, so that when once the Thames was well cleansed out, and the embankments made, he did not consider there would be much deposit. I do not imagine that the water from above Teddington has very much to do with the scouring of the Thames below, except during heavy floods.

3092. Supposing it should at any time be determined to take an extra 100,000,000 gallons from the Thames, and it were at the same time found that it was necessary to provide for those special occasions on which the flow would be reduced below 400,000,000 gallons, have you considered whether there would be any difficulty in making provision by reservoirs in the higher reaches of the Thames to supply the requisite quantity during the periods of deficiency?—I believe reservoirs might be made in the upper districts of the Thames which would supply a very large deficiency in very droughty seasons; it is merely a question of the expense of carrying them out.

3093. Would not the space upon which any reservoirs could be made, be naturally governed, first of all by the necessity of placing them upon impervious strata, such as part of the Oxford clay and the London clay. Of course you could not make such reservoirs upon the chalk?—No, of course not.

3094. You have not gone into the question to see whether such reservoirs might be made as would supply that deficiency in times of drought?—I have gone into it to some extent, but not very minutely.

3095. Assuming in all these cases that the money was allowed to be expended, could such a supply be obtained by carrying drifts to a large extent into the chalk?—I think that it very probably might, the volume that you might get from a drift is determinable in the same manner as the volume that you can get from a well. It is restricted in quantity by the length and breadth of the drift, and questions of that kind; by carrying a sufficient number of drifts and having them under control, I think a supply could be at command, so as to keep up the flow of the Thames at Kingston to one uniform volume of 500,000,000 or 600,000,000 gallons per day.

3096. (*Chairman.*) When you speak of having those drifts under control, do you mean that you would stop up the ordinary outlets of the chalk?—No, not the outlets of the chalk, but the outlet of the drift when you do not want it.

3097. How would that act with regard to the storing power, because that must be fed by the rainfall?—Yes, no doubt the storage must; the chalk is as completely a reservoir as any artificial reservoir in the country.

3098. It takes it up as a sponge?—Yes, and it is quite possible to tap that reservoir just as you can an ordinary artificial reservoir, keep the discharge from it under control, and open your sluices and let the water flow out as you please.

3099. Supposing you had a very dry season, and were to tap that reservoir, you would have no surface supply?—That is the point; I believe that if the drifts were carried into the chalk with judgment, you might draw water from that part of the chalk in a very dry season without seriously affecting the discharge from other sources throughout the dry season into the Thames itself.

3100. (*Mr. Harrison.*) You form that opinion upon data which have been ascertained as to the rate at which the water travels through the chalk, namely, about six feet per day?—Yes, at the rate of six feet per day it passes from the surface downwards perpendicularly. I do not know at what rate it travels horizontally towards the outlet.

3101. (*Chairman.*) Have you observed any points in the area of the Thames which would be peculiarly adapted for the formation of surface reservoirs?—Above Oxford there is a large area of ground on each side of the river on the Oxford clay where reservoirs of a shallow character might be formed. I may mention that Professor Phillips suggested, when he gave evidence before our Commission at Oxford, that in the upper part of the Thames a system might be adopted of embanking the outlets of some of the tributaries so as to, as it were, throw back into the oolites and other permeable strata, a large volume of water, and have the discharge from the subterranean reservoirs in that way under control. It is quite a question whether that might not be done with success. He mentioned a case in which a friend of his in Yorkshire had adopted the plan of banking up a spring and forcing the water back into the permeable strata behind, and whereas the spring used occasionally to fail in very droughty seasons, he afterwards had a constant supply, as in that way he made the strata below the surface his reservoir. The only difficulty in the case of the upper Thames is that the tributary of the Severn which passes upwards from Stroud cuts much more deeply into the stratification than the tributaries of the Thames.

3102. You mean on the other side of the watershed?—Yes, and that if you back the water into the strata it is not at all improbable that you would be doing that to the benefit of the manufacturers of the Stroud valley.

3103. (*Mr. Harrison.*) I presume there is no doubt that a portion of that which now fills the Thames basin would find its way into the Severn?—Precisely so, as far as subterranean water goes the mere watershed is not the limit of the water supply, at least not invariably so.

3104. (*Mr. Prestwich.*) You stated, did you not, that during a portion of the year the quantity of water which passes by Kingston is above 1,000,000,000 gallons a day?—Yes.

3105. (*Mr. Harrison.*) In the year 1858 it appears to have been for 55 days above 1,000,000,000, then in the year 1859 it was the same for 87 days, and in 1864 the same for 73 days, those being the three driest seasons?—Yes.

3106. (*Mr. Prestwich.*) That is to say, there are a certain number of days in the year when the quantity passing by Kingston exceeds 1,000,000,000 gallons a day?—Yes.

3107. Would it not be possible to store a certain quantity of that water in reservoirs dug in the London clay between Windsor and Kingston?—I cannot say, but I think it very probable; there is a great deal of Thames gravel which is very porous.

3108. Supposing the Thames gravel to be from five to 12 feet thick, which is about the utmost thickness, with the London clay underlying it, would it be possible to form reservoirs in such gravel?—If the gravel is so shallow there would be no difficulty in doing it. Such reservoirs would be similar to those which have been constructed recently by the East London Waterworks Company in the Lea valley, the depth of which is not very great. There is a great fall on the Thames. Teddington Lock is about 24 feet above Ordnance datum. Henley-on-Thames, 40 miles from London, is 100 feet. Caversham, near Reading, is 125 feet above datum, 76 miles. Wallingford is 153 feet above datum, 94 miles. Sandford, near Oxford, is 186 feet above datum, 112½ miles. Godstone Lock is 201 feet above datum, 121 miles. Saint John's Lock, near Lechlade, is 245 feet above datum, 147 miles. Cricklade is 272 feet, 159 miles up, and Cirencester, 360 feet above datum, a distance of 166 miles from London.

3109. Would not it be possible to construct a reservoir in the neighbourhood of Abingdon, where there is little or no gravel?—Yes, all over that middle clay district there would be no difficulty. Possibly on the Thame there might be some suitable reservoirs constructed, they would be shallow, there would be no very deep reservoirs. Perhaps I may be allowed in further reply to question (3055) to mention that Mr. Stacy at Oxford gave us evidence that the ordinary winter discharge at Oxford was about 320,000,000 gallons per day, whereas at Kingston it is between 800,000,000 and 900,000,000 gallons per day, about one-third coming from the oolite which is shallow and extremely free. In summer at Oxford the ordinary discharge is about 73,000,000 gallons per day, and at Kingston the ordinary discharge is about 600,000,000 gallons per day, the part from above Oxford being only about one-eighth instead of one-third as in winter. This shows the rapid discharge during winter from the heavy rainfall on the oolitic district as compared with the steady discharge from the chalk throughout the year. The area above Oxford is about one-fifth of the total area above Kingston.

3110. Have you ever considered the question of a double supply, the one supply for drinking purposes and the other for other purposes?—I am not a water engineer, but I am of opinion that the complication of gas and water pipes and sewers in London is quite sufficient without introducing another set of pipes; but in the evidence upon the river Lea, Mr. Muir stated that the New River Company have power now to take and the means of pumping or abstracting water from the Thames for sewer flushing, surface cleansing, and similar uses, and by carrying out separate lines of mains they could supply it with great advantage for purposes of that kind, distinct from the domestic supply, which would relieve the volume taken from the Lea to a very great extent, and be a benefit to the metropolis.

The witness withdrew.

The witness subsequently forwarded to the Commission the following table:

TABLE showing the MONTHLY RAINFALL, from January 1855 to June 1866, at Cirencester and Kingston-upon-Thames, and the Monthly Average; also the Number of Days in each Month upon which a Rainfall was recorded at each of these Places.

Dr. E. A. Parkes.

Dr. EDMUND A. PARKES examined.

3111. (*Chairman.*) Will you kindly state to the Commission the public appointment which you hold?—I am the Professor of Military Hygiene in the Army Medical School at Netley.

3112. Have you long held that appointment?—For the last seven years.

3113. Of course your attention has been directed to questions in relation to the health of the troops and the effect of water upon the health of the troops generally?—Yes.

3114. Can you give the Commission information as to any experiments which you have tried with regard to the use of comparatively pure water and waters of different degrees of hardness, or soft water, where you have had the means of testing the effect of soft water and hard water upon the health of the troops?—I have got a good deal of evidence together as to diseases which may be communicated by water, not only to the troops but among the civil population. I have made a list of diseases, all of which are occasionally communicated by means of water, not solely communicated by water but occasionally. For example, typhoid fevers; of which I have collected about 23 instances of local outbreaks of severe typhoid fever, and some six or eight more, the particulars of which I have not got, are known to me arising from water impregnated with typhoid sewage, or possibly with simple sewage.

3115. When you speak of typhoid sewage do you mean sewage from persons suffering from typhoid fever?—Yes.

3116. Can you detect that after its mixture with the water?—Not by any chemical re-agents.

3117. But under the microscope have you the means of detecting it?—No, there is no possibility of determining the particular substance which causes the fever in other persons. We only know the effect produced upon other persons, and no doubt it is from that cause.

3118. How did you ascertain that those outbreaks were due to water impregnated with typhoid sewage?—On account of the cases immediately following that impregnation with typhoid sewage. I do not wish to deny that simple sewage might produce the same disease, but that is a question still undecided.

3119. Have you the means of tracing the discharge of that class of sewage into the water, and the results following in fever?—Yes.

3120. Have you obtained many confirmatory results from that observation?—There have been altogether a considerable number of cases now placed upon record by different writers of such an effect following the passing of typhoid sewage, or possibly of simple sewage into drinking water. We had a case in the neighbourhood of Southampton only this last year, in a young lady's school, where a drain pipe passed within three feet of the well; at the point nearest the well the soft ground below the drain pipe had given way, and the pipe had sunk, and the sewage passed into the water of the well. Immediately following that was an outbreak of typhoid fever which affected something like 80 per cent. of the population, that is to say, 18 or 19 persons were affected out of a

population of 24 or 26 ; there were several deaths, and many of them very severe cases. In that case it was impossible to prove whether or not it had been typhoid sewage passing into the well ; but the impregnation of the water with sewage was certain and coincident at that time, and that, coupled with several cases of the same kind, seem to show that the outbreak of the fever is owing to the impregnation of the water with sewage.

3121. Would not the discharge of sew ge into any water which was the source of supply for domestic purposes favour the development of such zymotic diseases. I am not speaking now of typhoid fever sewage only, but of ordinary sewage ?—That is the general belief certainly ; there may be still a little doubt whether that is really the case. For example, in the instance of cholera, it was formerly believed by most medical men that the impregnation of drinking water with sewage would predispose to cholera at any rate ; but during the last year in Germany there have been a good many instances recorded in which very impure water had been drank during the whole period of the cholera epidemic without apparently producing any predisposition to cholera, I mean water impregnated with common sewage, not choleraic sewage ; the inference rather being at present that choleraic sewage must pass into the water to produce cholera. So that I should hardly like to express an opinion too positively as to the effect of sewage predisposing to zymotic diseases.

3122. Supposing that the condition of the atmosphere is favourable to the development of cholera, and that in addition to that the patients take to drink water polluted by sewage, would not that have a tendency to develope it with great rapidity ?—I should certainly think so, and that is the general belief, and it may be probably true.

3123. As far as your special observation has gone, in all cases where there has been a discharge of human excreta into water where the parties have been suffering from typhoid fever, that has generated disease in every district where the water has been taken for domestic purposes ?—It has not generated typhoid fever in all cases, because in some cases it has generated diarrhœa and dysentery ; typhoid fever has prevailed in some cases and not in others, and therefore that is an argument in favour of the view that it requires the typhoid sewage especially to pass into the water for the development of that particular fever, and that simple sewage will not cause it. But the question is surrounded with difficulties ; it is so difficult to get reliable scientific evidence that it is still *sub judice*.

3124. Have you had any means of forming a judgment as to the value of hard water as compared with soft water for drinking purposes ?—With regard to the effect upon health of the use of hard waters, distinguishing between the carbonate of lime water and the sulphate of lime, and sulphate of magnesian waters, the carbonate of lime waters appear in some cases certainly to produce some effect upon health ; for instance, dyspepsia, and they do not agree with some class of persons, whereas to others they appear to be quite harmless. There is a large population living upon chalk water, and we cannot trace any very decided effect upon their health in the production of any class of disease—calculus or anything of that kind, but at the same time persons do sometimes suffer from indigestion.

3125. What degree of hardness would, in your judgment, be a safe water, taking an average constitution ; some people will live in spite of difficulties ; their resistive force being such that nothing seems to effect them, but my question has reference to an average constitution ?—I do not think with regard to pure chalk water that there is any evidence that a moderate amount of carbonate of lime in the water does any harm, certainly not on the large scale ; in some individuals it produces indigestion.

3126. Would 16 or 20 degrees of hardness be prejudicial ?—I think that that degree of hardness would be certainly prejudicial. I think that very probably it might disagree with a great many persons ; but supposing it reached to 8 or 10 or 12 degrees of hardness from carbonate of lime, it might be considered probably good water as far as that was concerned, but I should draw a marked distinction between that and the hardness arising from sulphate of lime or sulphate of magnesia or chloride of calcium, which would certainly disagree in much smaller quantities, so that the goodness of water for drinking purposes I would estimate according to its permanent hardness rather than according to its temporary hardness.

3127. Are you acquainted with the waters that are supplied to the metropolis by the several water companies ?—Yes, I know them very well.

3128. Take the Southwark and Vauxhall Company for example, the total hardness of their water is 17·7 ? —Yes, but I do not know how much of that is permanent. The table of Dr. Frankland does not enable me to see how much is permanent. The total hardness merely is put down, and the other ingredients that are stated do not allow me to tell how much of that is permanent, but I suppose that it would be four or five degrees.

3129. (*Col. Harness.*) How do you distinguish between permanent and temporary hardness ?—Simply by boiling ; permanent hardness is that which remains after boiling. Supposing we have a water containing carbonate of lime, sulphate of lime, and magnesian salts, the hardness after boiling will consist of a certain portion of carbonate of lime, two grains per gallon held in solution, and the remainder of the hardness arises from the sulphate of lime, the sulphate of magnesia, and the chloride of calcium. That we call permanent hardness which we cannot break down by boiling, and that water certainly is worse than the carbonate of lime waters, which lose a great part of their hardness by boiling. Consequently, many persons living on carbonate of lime waters, for instance at Chatham and such places, take comparatively but little carbonate of lime, because they take the water in tea, and lose a great deal of the carbonate of lime ; even after standing the water loses a great deal of the carbonate of lime, so that in tea they would take it tolerably free from carbonate of lime ; that would be different from water of permanent hardness.

3130. (*Chairman.*) Have you had an opportunity of witnessing the effect of different waters upon the troops when moved from one station to another ?—I have seen reports upon that subject. I am stationary myself, and I have not made any observations upon that point.

3131. Can you give the result of the experiments of changing troops from one water to another ?—At present in the army they take a great deal of care with the supply of water ; the water is constantly examined, and pure water only is issued to the troops.

3132. When you say "pure water," do you mean soft water ?—I mean water especially which is free from organic matters ; whether it would be soft or not would depend upon the district, but water which does not contain any decided impurity of any kind, and the greatest care is taken at present, so that with regard to the army serving at home the influence of bad water is almost perfectly excluded. Now and then instances occur in which wells become impregnated, but the water is always examined by the medical officer, and any suspicious water is laid aside, so that it is almost impossible now to bring any evidence of disease amongst the troops arising from water.

3133. We may assume of course that any organic impurity would be objectionable in water, especially sewage ?—Yes.

3134. But supposing the water was equal in purity and free from organic matter, does the question of simple hardness or softness enter into the consideration of those whose special duty it is to care for the troops with regard to the kind of water that they should use ?—In all cases we would prefer a soft water if it were possible to obtain it ; and if the water were permanently hard, to a large extent that water

Dr. E. A. Parkes.

9 May 1867.

would be reported upon unfavourably, and better water as regards that property would be procured if it were possible.

3135. Do they resort to any means of softening the water where they are unable to obtain soft water?—In one instance it is done, at the Herbert Hospital at Woolwich where they employ Clark's process to soften the water. In that case it is carbonate of lime water and it is softened to some extent before it is distributed in the hospital. I believe that that is the only instance in the army.

3136. (*Col. Harness.*) Did they do anything with the Chatham water?—No, the Chatham water is very pure chalk water containing scarcely a trace of sulphate of lime, but a large quantity of carbonate of lime, 16 or 17 grains.

3137. (*Chairman.*) Speaking generally, you are of opinion that the mere presence of carbonate of lime or 15 degrees of hardness would not be injurious to health?—With 15 or 16 degrees of carbonate of lime hardness I should say that it would be hard water, and with some persons it would disagree and produce dyspepsia. I think it should not exceed 10 or 12 degrees if possible. At the same time I should wish to state that one would prefer water free from that even, if it were possible to get it.

3138. For all other sanitary purposes I presume there can be no question that soft water would be preferable?—No question at all.

3139. Has your attention been directed to the means of storing water in vessels of slate, or lead, or iron?—To some extent, but it has been on a small scale.

3140. What is the effect of soft water on lead?—It dissolves it in considerable quantities, particularly if the water contains much oxygen.

3141. Is that effect continuous or only at first?—I believe it is continuous.

3142. Is it not found that when lead becomes coated the absorption does not go on after a certain time?—The chalk waters deposit largely on lead, and some of the other lime waters also, but the soft waters continually take up lead, so that the pipes and cisterns are eaten through with soft water. We have many instances of that in our neighbourhood, where we have soft water, and the use of lead has been entirely discontinued, so rapidly has the water eaten through the lead; and iron pipes are corroded by soft water more rapidly than by hard water, because they become corroded like lead pipes. It is a matter of great consideration with regard to the supply of water to London that although lead pipes are almost universally used they have now become nearly harmless by being coated over by the deposits from the hard water, and it would become very hazardous if means were not taken to secure the pipes against the action of soft water.

3143. Are you acquainted with the mode which is adopted by several of the water companies for the purpose of filtering their water?—I know most of the plans which are in use I think.

3144. Do you think that the system of filtration which is adopted is likely to prove beneficial except in removing that which is held in mechanical suspension?—I believe it does not do much if anything more than that, it merely removes mechanically the substances floating in the water to some extent, not in all cases.

3145. That which is held in solution will pass through unaffected?—Yes, nothing will take out substances in solution I believe unless the filtration be conducted with other substances than those commonly employed on a large scale, unless they employ animal charcoal especially.

3146. But the mere rough sand filtration would simply have a tendency to free the water from mechanical impurities had in suspension?—Quite so.

3147. In the paper you have been good enough to send to the Commission you state that the purest and most wholesome water should contain no suspended matters, and that the amount of dissolved organic matters in it should be under one grain per gallon, and of dissolved mineral matters under seven grains per gallon?—In my minute of the evidence that I proposed to give I attempted merely to form a sort of standard which might be understood by the public as to what waters were best. It seems desirable to give the public some sort of idea what waters may be used or what may not be. There are difficulties in forming a standard which may not be objected to by scientific men on account of the difficulty of making the evidence very precise upon such a point as this, and therefore such an enumeration of waters as I proposed must be received merely as an attempt, without pretending to anything like scientific accuracy; but I think that the following standard of water will convey the most important points connected with the supply of drinking water. I would propose to form a class of "wholesome waters," under which two sub-classes of waters may be included, first, the purest and most wholesome water which is free from suspended matters, and contains very little dissolved organic matters, say under one grain per gallon, and that probably vegetable, and of dissolved mineral matters under seven grains per gallon. That will include all the best waters supplied from the primitive rocks, and from some of the sands which contain under that quantity of mineral matter, and is probably the purest water on the whole which can be obtained in that way.

3148. How would that compare with the Loch Katrine water?—It would include the Loch Katrine water, which contains under one grain of organic matter per gallon, and two or three or four grains of mineral per gallon. It will also include the water of some of the sands, such as the Bagshot sands, which contain under seven grains per gallon, which may be put in the same class. The Loch Katrine water is the purest and most wholesome water which can be obtained in that way, and rain-water after filtration might come under the same standard. Then the second sub-class in the first order would be what I would call pure and wholesome water to which no objection can be taken, I believe, in a sanitary point of view, but which is not so pure as the former. This water is also free from suspended matters, having dissolved organic matter under two grains per gallon, the greater part of that being vegetable. Of dissolved mineral matters it would contain under 12 grains per gallon, consisting principally of carbonate of lime, and alkaline carbonates, and chlorides. That second sub-class would include the best chalk waters, which are often very free indeed from organic matter. Then the second grand class I would make, I would propose to call "usable waters;" waters which cannot, perhaps, be very much objected to, not so good as the former class, but yet which in many cases might be used, and which would not produce, perhaps, any bad effects. Those are all waters with no suspended matters or suspended matters easily separated by the coarse filtration usually resorted to by the water companies. The organic water would be chiefly vegetable, but it should not exceed three grains per gallon, owing to the diseases which would probably arise if it exceeded that quantity, and if the organic matter is apparently of a mineral origin it ought not to exceed two grains per gallon. Then it should contain mineral salts not exceeding 20 to 30 grains per gallon, and consisting of a class of salts which do no injury to the system, such as alkaline carbonates, alkaline chlorides, chloride of sodium, and chloride of potassium, in less quantity, and possibly a little carbonate of lime also.

3149. In all those three classes when you speak of organic matter you exclude sewage in any and every form?—Yes, I would exclude sewage throughout. The third class would be what I would call "suspicious water," which would be any water with much suspended in all which would be separated readily by matter filtration. Such a water as that would coarse probability contain either fine particles of mineral matters, which are hurtful, such as clay, or possibly it might contain

suspended organic matters very finely divided, and not very readily separable by filtration. It might contain dissolved organic matters, vegetable and animal, amounting to about three or four grains per gallon, and mineral matters of large amount, such as alkaline and chlorides, carbonates, and carbonate of lime in large amount, that is to say, perhaps over 9 or 10 grains per gallon, or sulphate of lime or magnesia, and chloride of calcium or magnesium in certain quantities; all those I should consider make a water suspicious; or if it contains any indication of nitrites, nitrates, ammonia, &c., showing that organic matters had passed into the water and had there been oxidized; any indications of that kind I should consider would bring the class under the head of suspicious water. Then the fourth class would be "impure water," which would include any turbid and bad smelling water with suspended matters not easily separated by coarse filtration; also dissolved organic matters above four grains per gallon, especially if of animal origin, large quantities of mineral substances, especially of sulphate of lime and sulphate and chloride of calcium and magnesium, which all give permanent hardness to the water, or large indications of nitrites, nitrates, fatty acids, ammonia, &c., all of which indicate the passage of organic matters, animal in all probability, into the water. To sum up I would propose as a popular division these classes.

1. Pure and wholesome waters.
2. Useable waters.
3. Suspicious waters.
4. Impure waters.

The definition of each would be as above stated.

3150. (*Col. Harness.*) Under which of those heads would you put the London water?—I should put the London water under head No. 3, suspicious.

3151. Would you do that because there are indications of nitrates?—Yes; I should call any water containing large indications of nitrates and nitrites suspicious water. Such indications may, however, come from water not impregnated with sewage, as some soils give off nitrates and nitrites.

3152. (*Chairman.*) Is the result of the Board of Health analyses of the London water sufficient to enable you to judge of its character?—As far as regards nitrates and nitrites and ammonia are concerned, it is quite sufficient to enable one to judge.

3153. Should you call it suspicious water?—Yes. I should certainly call it suspicious water.

3154. Which is the first of the London waters in Professor Frankland's analysis?—The first water is the Chelsea water, which contains nearly 28 grains of solid matter.

3155. Would you call that suspicious or impure?—I should call it certainly suspicious water. It contains nitrates, nitrites, and ammonia in some quantity, and knowing that such substances exist only in small quantities in pure Thames water I conclude they are derived from sewage.

3156. Will you be good enough to add to that statement under which denomination you would place the water, whether suspicious or impure?—Suspicious.

3157. (*Mr. Harrison.*) Allow me to call your attention to this report of Dr. Frankland's, in which, referring to this particular table of the analysis of the waters, he says, "By gradual oxidation partly in the "pores of the soil, partly in the Thames or its "tributaries, and partly in the reservoirs, filters, and "conduits of the Chelsea company, this sewage con- "tamination had been converted into comparatively "innocuous inorganic compounds before its delivery "to consumers." That has reference distinctly to this analysis in the weekly return of the Registrar-General; you, perhaps, could hardly say whether you would confirm that view of Dr. Frankland's or not?—I think that the mere presence of nitrates and nitrites in water in small quantities would not be hurtful at all; their importance is as indicating their source and showing that there must have been contamination, probably by animal organic matter, in most cases sewage, and of course rendering the chances of such organic matter passing in in sufficient quantities to affect the health very probable, but when such organic maiter has been oxidised, then no doubt it becomes, at any rate in most cases, harmless.

3158. (*Mr. Prestwich.*) Would it not be very difficult to distinguish the origin of the nitrates and nitrites, whether arising from sewage or from the rain, or from the earth, or from vegetation?—From the rain the quantity would be small; indications of nitrites will be found in rain water and in water from the earth, and there is a certain amount of difficulty in determining from what source they come. In our neighbourhood, for example, there is a sort of dark soil under the sand at certain points which contains very large quantities of nitrites and nitrates not derived at all from sewage, and the water drawn from those strata gives indications which might be taken in the first instance for sewage. That mistake could only be avoided by knowing the soils which furnish the water. In the case of the London water, the Thames water, which is furnished in such large quantities from the chalk, will, I believe, in no case without sewage contamination, give large indications of nitrites and nitrates; there would not therefore be any difficulty in supposing that the indication of nitrites and nitrates would be owing to organic matter which had found its way into the water from the sewage, still there would be a difficulty in all cases in saying at once that the presence of nitrites and nitrates in water was owing to sewage matter or any other accidental organic matter.

3159. In the case, for example, of forest lands, even at a distance from towns, have not instances been known of water flowing from such forest lands containing quantities of nitrites and nitrates?—I have no doubt of it; in fact, there is scarcely any water in which some small quantity of nitrates does not exist.

3160. (*Chairman.*) Sewage is the most dangerous parent of those things, is it not?—Yes. But any indication of them should lead at once to an examination, so as to trace the origin of nitrates and nitrites, and the water would be suspicious in the proportion that it contained any large quantity.

3161. (*Mr. Prestwich.*) It would not be a certain inference that it was from sewage?—Certainly not.

3162. (*Chairman.*) Your attention, I think, has been directed to the question of a constant or an intermittent supply of water, and its advantages or disadvantages. Will you favour the Commission with your views on that subject?—There are great sanitary advantages in a constant supply, namely, in doing away entirely with the house storage. The house storage entails a great chance of the water being impure, either from the cisterns being allowed to get filthy or from substances finding their way in from the overflow pipes communicating with sewers and drains, and gases forcing their way back through imperfect traps. All these evils the constant supply entirely does away with, but the disadvantages of the constant supply are certainly the very great quantity of water that is wasted, and the occasional failure at times when it is very important indeed to have a large supply of water. For example, last year, in Southampton, in the time of the cholera, when it was extremely important to have the drains well flushed, and everything carried out, we had rather a failure in the supply of water in the low parts of the town. The population in the higher part of the town being nearer the reservoir used a very large quantity of water owing to the dryness of the season, also their gardens required a large quantity of water, and this was taken from their constant supply. At the same time there happened to be also some alterations going on in the pipes and in the machinery, which also lessened the quantity. The consequence was that we were unable in the low parts of the town for several days during the prevalence of the cholera to ensure a proper quantity of water passing through to the sewers.

3163. That would be rather an accident when the

Dr. E. A. Parkes.

9 May 1867.

works were out of gear and would not affect the general principle of constant supply?—No doubt, but at the same time there is always a danger of an insufficient supply at times. There is scarcely any town that can ensure a supply so large as to enable it to meet all the demands of a large population.

3164. For example, supposing a town had a reservoir in a convenient place, giving a sufficient head to distribute the water all over the town, within a short distance, with 21 days supply stored, or with a capacity to store 21 days supply, would you be in doubt as to the efficiency of the constant supply as compared with the intermittent supply?—It would be necessary to know what in that case you would take to be the daily supply per head of the population.

3165. Assume, for example, 40 gallons per head for manufacturing and all other purposes?—Then of course it would depend upon the size of the town.

3166. Assuming a population of but 5,000 or 20,000, you would have a supply equivalent to that which would be distributed under the intermittent system and stored in the houses, but you would have it placed at every man's house, so that he could take it as he required it?—I believe that the system of constant supply is by far the best if you can do away with the principal chance of failure by apportioning out large towns into smaller ones and having the constant supply only applicable to a certain number of houses by a particular set of pipes, that is to say, by having numerous reservoirs which would be equivalent to supply say 5,000 or 10,000 people, so that at any time you may be quite certain that you have not only got a supply for that particular district, but that it cannot fail in consequence of an increased demand which may be made by other districts upon a single reservoir.

3167. (*Chairman.*) Your fear would be as to the capacity of the public or public company to supply the whole district in a case of emergency such as occurred at Southampton?—Quite so, in the case of any large town. In the case of a small town I conceive that there would be no difficulty in the supply.

3168. Assuming that you have an ample supply for the whole population of a town, are you of opinion that the system of constant supply for all sanitary purposes is infinitely superior to that of an intermittent supply?—Quite so, if you can get over the practical difficulties and the enormous waste, but I think that if you have the coustant supply it must be understood that there is to be no stint in the water in any part of the district at any time as there appears to be in some towns which are supplied with the constant service.

3169. When you speak of the seeds of disease being conveyed in water, would boiling have any effect upon that water, so as to destroy the germ which conveys from one patient to another choleraic or any other disease?—Exact experiments upon such a point as that are impossible. You cannot make any experiments as to whether or not water would convey it after boiling; you can only estimate it by chemical agencies. The effect of boiling is not very much to destroy organic matter in water; it may destroy some, but it does not destroy a great deal. Boiling, *per se*, is not such a purifier of water as is sometimes supposed. It throws down a great deal of suspended matter; it throws down carbonate of lime if it exists in the water, which carries down also suspended matter; but dissolved organic matter is not much destroyed by boiling.

3170. But the question is whether by subjecting this germ of disease to heat for a certain period its vitality would be destroyed?—I could give no answer to that, because I do not think that any experiments could ever be made upon such a point. It could only be done by a series of observations of people, with respect to people drinking the water who had boiled it and people drinking it who had not boiled it. With regard to cholera and typhoid fever no observations have been made as to the effect of boiling destroying the germs of disease.

3171. There has been an experiment recently made by a French professor, with regard to the seed of a plant which was boiled for four hours and which yet retained its vitality?—It is almost impossible to say; speaking in a true scientific spirit, namely, from evidence, whether boiling would or would not destroy the cholera or typhoid germ in water.

3172. You know of no means by which water of a suspicious character could be deprived of those injurious compounds?—It can be very readily deprived by filtration of organic matter, and I presume of those compounds also, but I have no evidence that water which would produce cholera in one person when subjected to proper filtration would not produce cholera in another. I think it is very likely that it would not, but of course such an experiment as that cannot be made, but filtration through animal charcoal and through many filters now in the market (and there are four or five admirable filters in the market) will take out a great quantity of animal matter from the water. For example, I have with me a confidential report made to the War Office of some experiments of my own which I have made upon the chief filters in the market. I find that some of them will remove of organic matter (sewage matter that is to say) from water, as much as 95 per cent. and that others remove 89 per cent. and others 83 per cent.

3173. In the case of the 95 per cent. is that a charcoal filter?—It is a charcoal filter. It is not one of the common charcoal filters. The worst filter that I could get which might be considered a filter at all, and which was a charcoal filter, removed 69 per cent. of organic matter from the water, so that a very considerable effect is produced upon water by proper filtration on a small scale; and it is to be presumed that it is scarcely possible that any organic substance carrying a germ of disease could escape through such a filter; but in the absence of experiments, I would not undertake to say that it would not.

3174. Then the mere boiling of water would add little to its safety?—I do not think that it would add much. I have made a few experiments upon that point, and I was able to detect some organic matter after boiling. Suspended organic matter is thrown down certainly.

3175. (*Col. Harness.*) You assume that the seed of disease, whatever it is, remains in the organic matter?—I cannot conceive that mineral matters of any kind produce such diseases as typhoid fever or cholera.

3176. Might not something which is not organic matter affect the water so as to make the water unwholesome, although it is not separable from the organic matter in the water?—Then it would be some substance which is not dead organic matter but live organic matter. It must be something which I should class under the head of organic matter.

3177. (*Chairman.*) Is there in your judgment an objection to the Thames basin as a gathering area for water by reason of the high state of cultivation in some parts, and from the manuring that it undergoes?—Yes, I think there is a very great objection. No doubt the effect of water passing through a soil with manure is to cause a very rapid oxidation of the organic matter, and a very large quantity is converted into nitrates, and nitrites, and ammonia, but there is a limit to that, and it is impossible to insure the safety of water where there is the possibility of contamination on a large scale with organic matters derived from sewage.

3178. If it passed through a sufficient depth of earth it would be deprived, would it not, of this matter?—The earth would be a great purifier, no doubt.

3179. But if the soil is saturated at the time the manure is placed upon it, and a sudden fall of rain should follow to wash it off without its passing through that strong deodorizing soil, it would carry with it a great deal of objectionable matter?—Yes, there is constant danger in that respect.

3180. You have observed of course the inherent

power of water to purify itself by exposure to the atmosphere?—Yes.

3181. Have you observed in a case where sewage has been discharged into a river that after running for three or four miles the effect of that sewage has been destroyed?—Yes, we have that in the case of the Southampton water supply; some sewage passes into the Itchen river, but it is quite destroyed by the time the water is distributed in Southampton, at least there is no detectible quantity.

3182. What is the distance?—The distance is six or eight miles. I could not undertake to say the distance in which water would purify itself in that way, but there is no doubt that it does purify itself, although in what distance or what time or under what precise circumstances I could not say.

3183. I presume that the sewage probably by the action of the water and the atmosphere would really be broken up into other elements of a less injurious character?—Yes, broken up into compounds of nitrogen and ammonia, nitrates and nitrites.

3184. You do not get rid of it, you have it in a different form?—Yes.

3185. And in a less objectionable form?—Yes, in a form I presume quite unobjectionable in a small quantity. A very large quantity might be irritant, but in a case in which they would be in water not very largely impregnated with sewage I should think that they would not be hurtful.

3186. Do you think, taking the upper part of the Thames as a gathering area, that any injurious result from manuring or other washings into the river would by the course of such water down the Thames be somewhat neutralized?—I think that very likely it would be neutralized to a very considerable extent. That would rather depend upon the amount passing in; if any experiments could be made as to the amount of manuring and the number of acres that would furnish sewage matter, and the amount of sewage matter which would pass in, and the rapidity of the flow of the Thames at different parts of the year, and the volume at different times in the year, we should be able to form a better idea. It would be modified by a great many circumstances.

3187. But there would in your judgment be a process of purification going on?—Yes, it would be simply a question of degree.

3188. Dependent upon the quantity of pollution in the volume of water?—Yes. On that point it might be possible to make experiments. The only real answer for such a question would be the experiments made as to time and distance and the amount of oxidation which would go on under various circumstances connected with the lower waters of the Thames.

3189. If water is soft when it is taken into a culvert either at the head of the Severn or in the lake district, are you aware whether in its transmission to the metropolis through tunnel or open cutting, any chemical change would take place in that water with regard to its quality?—In the flow of water changes do take place if the water is exposed to the air. For the most part the chalk waters deposit some portion of their carbonate of lime. On the other hand, in passing through pipes of any kind, the nature of the pipes might possibly furnish substances to the water.

3189. They take up iron, do they not, for example?—Yes, most waters would do so till the iron had got covered with a deposit.

3190. (*Mr. Prestwich.*) In speaking of those diseases produced by the impurities of water in cases in your experience were they well water, or river water, or spring water?—If you will allow me I will enumerate the various diseases which have been traced to the impurities of water. Dysentery has been traced in a good many cases to the effect of water, both river water and occasionally well water, and diarrhœa in the same way. Many rivers, particularly those loaded with suspended matters or containing a quantity of sewage matter, have produced dysentery and diarrhœa. Many of the American rivers, and some of the Russian rivers, the Volga for example, are loaded with sewage, and the water of the Nile in certain cases produces dysentery.

3191. (*Chairman.*) When you speak of that effect of the Nile water, does it arise from the large amount of vegetable matter in the water?—No, the Nile water is very pure above Cairo, but lower down it becomes impregnated with sewage. At certain times of the year the quantity of water in the Nile is small, and then it produces diarrhœa and dysentery.

3192. Is not there a large amount of decomposed vegetable matter in the Nile?—Yes, no doubt there is some, but in some specimens of the Nile water the vegetable matter is very small. No doubt at different times of the year it would vary in that respect. To resume the statement of the diseases, cholera is produced occasionally by water, not always, but the choleraic poison is carried in water, and marsh and malarious fevers also.

3193. Do you concur in the view entertained by Dr. Farr and others with regard to the cholera water so called, of a kind of milky colour which is observable in the water at certain elevation?—I do not think I am quite aware of the point.

3194. There is a diagram showing the effect of elevation upon the spread of cholera and how that peculiar cholera germ is suspended at a certain elevation and how the disease developes itself at a certain height; have you seen that diagram?—I am not acquainted with it. I know his observations on the effect of elevation on the spread of cholera, but that is apart altogether from any question of drinking water.

3195. (*Mr. Prestwich.*) You stated, did you not, that the river for example at Southampton had received the sewage of towns above the source of supply to Southampton?—Yes, sewage applied to the land.

3196. Not town sewage?—I believe that it does receive some of the town sewage of Winchester.

3197. But by the time it reaches the reservoir at Southampton the water is so oxidised that it becomes comparatively pure?—Yes.

3198. Therefore your observation with regard to the spread of disease from water from wells and rivers applies, I presume, to cases where there is a decided impregnation at the spot?—Yes.

3199. And where the flow has not been sufficient to produce the oxidation?—Quite so.

3200. Can you give any instances of the effect of water upon the health of the troops arising not from sewage contamination or organic contamination but from a change in the character of the water in its mineral constituents?—There are various stations where the water is not particularly good, and where it has produced an effect upon the health of the troops; for instance, at Gibraltar the well water is very impure, and the troops have been obliged to be removed.

3201. The greater part of the troops I presume in this country are located in districts where the water is of a moderate degree of hardness; for instance, Dover, Portsmouth, Southampton, Plymouth, and the greater part of Ireland?—Yes, and at Chatham. At Southampton we have no troops, and at Aldershott, the troops are upon soft water. At Chichester the water is hard and at Colchester it is hard. For the most part they are chalk waters.

3202. Have you known instances of any ill effects from the use of such waters?—Not of the good chalk waters.

3203. Have you known any instances where troops have been located in districts where they have been using water of a moderate degree of hardness, and have suffered when they have been removed to a district where the water was soft?—I have never seen any reports of that kind.

3204. Are there troops located at Aberdeen?—There is only a small number at Aberdeen except when the Queen is in the Highlands.

3205. You have no means of knowing the effects of the use of such waters?—No.

Dr. E. A. Parkes.

9 May 1867.

3206. (*Col. Harness.*) The removal from Chatham to Manchester would be a good test, have you known any instance of that?—No, but I could make inquiries. If any medical officer had reported that the health of his soldiers had been at all injured by transference from water of one kind to water of another kind, I think it would have been reported, but I can make inquiries upon that point, and add it to my evidence.

3207. (*Mr. Prestwich.*) You have mentioned the case of Woolwich where they use Clark's process for softening water, does not that arise from the circumstance that the waters there are unusually hard, and are derived from wells, the water of which is of a greater degree of hardness than is furnished by the waters in the chalk districts?—Yes, it is hard water, and the water having to be supplied to the hospital, and it being considered of importance to have pure water for the patients; I believe that that was the chief consideration which led to the use of that process, but the water is very hard which is derived from the wells there.

3208. Should you not consider that streams flowing through a chalk district such as the Downs, where they would be free from all sewage contamination, would be perfectly pure and good waters?—Yes; I have made a great many inquiries upon that point, and I believe that when it is a chalk water within certain limits, it is a harmless water, at least I have never been able to trace any ill effect upon health. But occasionally chalk furnishes bad water; for example, at Chatham, some of the wells there furnish very unwholesome water, containing a considerable quantity of sulphate of lime; therefore it does not follow that in every portion of a chalk district the water supplied by the soil would be a pure chalk water. In some of the well water at Chatham we have a large quantity of sulphate of lime, and even of magnesia, and in some cases indeed there is the presence of iron in considerable quantities.

3209. The tendency in waters furnished from the chalk districts is to part in a certain proportion with their lime, that is to say, water from wells from a chalk district would be of a much greater degree of hardness than water from a river flowing through the same district?—Yes, a river drawing its water from the chalk and having any length of flow would certainly part in the course of that flow with a considerable quantity of its hardness.

3210. Therefore the waters in the wells would be considerably harder than the waters in the rivers in the same districts?—Yes.

3211. With regard to the action of hard waters in taking up organic matters, could you give us any opinion with regard to the facilities of solution which such waters may have?—No, I have found large quantities of organic matters in all kinds of water. Some waters very free from mineral matters would take up organic matters very readily, and chalk waters and other lime waters will take up organic matters. I have not been led to suppose that there has been any difference in their degree of solvability of sewage matter.

3212. Are you aware whether a certain quantity of carbonate of lime may not in many cases be rather beneficial than otherwise to health?—I think that is again very doubtful. The fact is, that almost all kinds of food contain enough lime for the supply of the body, and the quantity of carbonate of lime supplied in water might no doubt be applied to the wants of the system, but I can hardly think that it would be necessary, that is to say, I do not think it should be an argument for the supply of chalk water that lime is thereby supplied.

3213. Some of the authorities both in this country and in France have been of opinion, have they not, that the presence of lime was rather beneficial than otherwise?—Yes, several have been of that opinion, but some of the chief arguments have been derived from the feeding of pigs, for example, by a French chemist, and it has been shown that his calculations have hardly borne that idea out. He supposed that the lime supplied in the water was really applied in the nutrition of the pig, but it was shown that enough lime was passing in the food to give all the lime that was really wanted.

3214. Provided it was not kept upon some particular food in which a certain quantity of lime was present?—Quite so.

3215. But apart from the use of lime for the formation of bone, I presume that the presence of lime as a slight alkali is combined with the carbonic acid in the water. Do you attach any importance to that?—I should not attach any importance one way or the other perhaps to it. There are certain persons who are not able to take carbonate of lime water from its producing in them constipation and dyspepsia, but they are a small minority.

3216. And that would hardly arise in the case of a population which has been accustomed to the use of such water?—I should think not.

3217. I see that one disorder which you mention is calculi; have you been able to trace that back to the use of water?—In Germany especially there is a very strong opinion in certain parts that the phosphate of lime calculi and calculi generally are more common in districts where the inhabitants use very hard waters, but in this country the evidence is so far negative; we have not many districts supplied with limestone waters or the magnesian limestone waters; most of our lime waters are chalk waters, and so far, I think, in this country there is no evidence of there being a greater amount of calculi than in other districts not supplied with this water, but in Germany and, perhaps, in France the evidence is stronger that the use of some of the lime waters may have an influence in the production of some of the calculi.

3218. Would that be in the case of water of an ordinary degree of hardness, or of an excessive degree of hardness arising from the chalk or from the presence of sulphates?—I believe especially from the large amount of hardness arising in most cases from the mixture of chalk and of sulphates, at least it is so in most of those waters.

3219. You mentioned, did you not, one disadvantage of the constant supply at Southampton, namely, that there were times when the supply was short?—Yes, that was the case last year, and that was in part owing to a temporary defect in the machinery, and they lessened the supply on that account; but, I believe, in other towns where they have the constant system, there have been difficulties in the supply from time to time.

3220. Do you know what the quantity of storage is at Southampton?—I could not tell that without reference, it is very considerable.

3221. Have you had opportunities of determining the quantity of water which it would be desirable to furnish to the troops per head?—That will entirely depend upon the way in which the sewage is disposed of.

3222. For all purposes I mean?—Including the washing away of sewage, and all purposes connected with washing, and the houses, and everything else, I generally estimate it at about 25 gallons per head per diem.

3223. (*Chairman.*) You think that that would be sufficient for all purposes?—Yes, for all purposes, I think, in this country.

3224. I suppose troops use a larger proportion of water than the ordinary population per head?—I am not aware that they do. There is a great deal of washing, but whenever they get plenty of water there is a good deal of washing going on.

3225. (*Col. Harness.*) Would that quantity include water constantly supplied to the latrines?—Yes.

3226. But you do not know in what proportion it includes it?—I believe, about from 8 to 10 gallons per head, and the remainder is water which is used for washing, cooking, and other purposes. At the same time I should say a much less quantity is used at some stations than that.

3227. Have you ever been at a station where the water was so scarce that it was obliged to be taken care of, such as it would be at Bermuda for instance?—No.

3228. (*Mr. Harrison.*) Taking generally the Thames basin, there is nothing in it that occurs to you as objectionable for general purposes in any water that would be obtained in that basin, assuming it to be free from sewage?—I am not aware that there is. At certain times of the year there is a little clay washed down, which makes it a little turbid, which is sometimes not very readily separated by filtration, but beyond that, supposing you consider the carbonate of lime in it unobjectionable, I do not see that there is anything in the water of the Thames, as far as health goes, which is objectionable.

3229. The water of which you have got an analysis in the table before you is water into which the sewage of many large towns, containing altogether a population of nearly 1,000,000 inhabitants, is now passed into the Thames direct?—Yes.

3230. Assuming that under the powers of the Act of last session all that sewage will be diverted in the first instance from the Thames and used upon land, would you not consider that the result would be that it would be very much purified beyond what it is at the present moment?—I have no doubt of that at all, but it is impossible to say what the amount of purification would be, because I do not know what the conditions would be of the irrigation of land in proximity to the river, or the amount of water which would pass through the land.

3231. All that would be laid upon the chalk and oolites would be almost entirely absorbed by the land, would it not?—Yes.

3232. But where the sewage is laid upon the clay it would come off more rapidly?—Yes.

3233. Do you think that if that plan were carried out there would be still an impurity in that water sufficient for you to say that it ought not to be used?—I should feel very great difficulty in answering that question.

3234. You seem to say now that from Dr. Frankland's analysis it is what you would call a suspicious water?—I should say so, because there has been certainly organic matter in it derived from sewage, and though that has been oxidized to a considerable extent, still, as showing previous impregnation, and as indicating that there might be a further passage of sewage into the water, and the possibility of a less degree of oxidation at certain times, I should call it a suspicious water.

3235. Then until that purification has taken place which is now in progress, and the water is analysed afterwards, you think that no opinion could be formed upon that point?—I should like to know whether it would be effectual or not in completely diverting the sewage from the Thames, and I should hardly think it possible to form any opinion upon that point.

3236. (*Col. Harness.*) Supposing that the sewage of Chatham was employed upon the meadows and gardens in the valley of the Medway, how would that affect the water supplied by a large well in the chalk?—It would be a dangerous experiment; it takes some time to penetrate through chalk, but we know it is penetrated. Some of the large wells in the lower part of Rochester are separated by a considerable distance of chalk, but they have become penetrated, and of course a constant supply of sewage upon the surface in the immediate vicinity of that well would be dangerous. The danger in the chalk, as in the sand, is in a channel being worn, and finally a considerable passage taking place into the well.

3237. (*Mr. Harrison.*) Do you think that in point of health the population of London generally suffer from any impurity in the existing water apart from any special case of cholera in the east of London?—I think that where the population of every town shows a considerable amount of diarrhœa and also of typhoid fever it makes one believe that there must be some impurity in the water at times, and the health of the population as regards those diseases of the intestines seems to be very much influenced by the purity or impurity of its water supply.

3238. If you had the choice you would prefer to go to such water as you could procure at a large expense, such as the Loch Katrine water?—Yes, if one had the opportunity, of course.

3239. Could you give any measure at all of the difference of value as regards the question of health between the two, that is to say, as between using such waters as are now used in London, and using such waters, if they could be got, as those of Loch Katrine?—I am quite certain that the health of the people would be improved considerably, but I could not give any numerical standard. I believe that most diarrhœa affections would disappear, and typhoid fevers would be diminished, and that the chances of cholera being conveyed by water would be almost entirely taken away. I can hardly conceive that there would be any chance of any conveyance of cholera by water.

3240. (*Col. Harness.*) Have you made any comparison as to the continuance of those diseases between two places where the waters were very different—between where the water was soft and where it was hard?—Not in large districts. People suffer from drinking impure water in either case from diarrhœa certainly. There has been some very valuable evidence given as to the effect of the change of water on dysenteric affections in Bermuda and the West Indies. Those diseases which used to be very prevalent there, and which were owing to the water, have disappeared almost entirely. At the present time in Jamaica, where there used to be so much dysentery, there is far less than there is at Gibraltar or in Malta, or in the Mauritius, and other stations of that kind.

3241. What has been the change in Jamaica?—The change has been the supply of good water, chiefly rain water. In many stations in the West Indies rain water is used, and in many places the carbonate or sulphate of lime well or river water has been entirely given up, and the effect has been a marvellous alteration in the health of the troops. I believe that that is the cause also now in Barbadoes and Trinadad. The improvement of the water has been followed by the disappearance of certain diseases.

3242. In the West Indies they have introduced the softest possible water?—Yes, wherever they could obtain it, either by springs or by rain water.

3243. (*Mr. Prestwich.*) Is there not almost a total absence of evidence with regard to the effect upon health of the use of such water as comes from the primary rock and from the calcareous districts apart from all question of the contamination of towns or sewage?—If in the expression calcareous you mean the carbonate limestone, or chalk, it is extremely difficult to get evidence upon that point at present. Our attention has been so little turned to the effects of water of that kind that I can hardly give you any evidence which would be satisfactory as showing that the inhabitants of primitive districts enjoy a better state of health than those supplied with pure chalk water, but at the same time the general bearing of all evidence is to show that the purer the water which is supplied to the system the better it is for the processes of the body, but I may say that that is only a sort of impression derived from the general study of disease and health, but it is almost impossible to bring forward statistical evidence as to the presence of disease here as compared with disease in another place which would be convincing.

3244. It is said that the inhabitants of mountain districts, for example, either Wales, or Switzerland, or Scotland, enjoy a better state of health than the inhabitants of a limestone district, such as that of the central part of Ireland. Have you any information on that point?—Our difficulty is in making all the circumstances equal. There is not only the question of food, but there is the concentration of the inhabitants, and the occupation and everything else has to be considered in addition to the water, and that

Dr. E. A. Parkes.

9 May 1867.

makes the comparison so extremely complicated that it is very difficult to give a decided opinion.

3245. (*Mr. Harrison.*) If the subject had been considered one of vital importance by the medical profession generally, do not you think it would have been proposed that it should be scientifically investigated by some specially appointed body either of medical men or chemists?—We must remember with regard to the effect of different things upon the health of the community in this country that it has only been the subject of investigation for the last 30 years. Till we began to have statistics of deaths we had not learnt to know the relative prevalence of the several forms of disease, and it was impossible to form any opinion as to the condition under which the people were living. We may say that these questions are almost in their infancy.

3246. Is it not your idea that it is an important question for scientific investigation?—I think it is a very important one, and I am certain that many diseases are communicated by the agency of water, and I consider that the effect of pure water on health is of the very highest importance; but if you ask me for evidence to give chapter and verse for everything, I should find a difficulty in doing so.

3247. Assuming that it were practicable to supply London with a water equal to that of Loch Katrine, supplementing the present supply, would not it be exceedingly difficult to arrive at any conclusion as to what it was worth upon any information which is possessed at the present moment?—At the present moment it would. I do not thiuk you could get any statistical evidence, and even after you supplied it there would be a difficulty of course in proving the case, because you cannot prevent other sanitary improvements going on at the same time, improvements in drainage and improvements in other things which might affect the health of the community.

3248. Would not the question be in a great measure governed by the opinion of medical men as to there being anything decidedly wrong in the present water supply, and in order to justify a complete change of the present system, should it not be based upon some decided evidence of defect in the present supply?—But at the present time the supply in London is known by chemical evidence to be impure, apart from any statistical evidence of disease.

3249. (*Col. Harness.*) Would you object to a site for a hospital where the water to be obtained was of the quality of the London water?—I should certainly say that the London water has been impregnated with sewage from the evidence of the oxidation of nitrogen, and therefore, being impregnated with sewage, I should think that there would be considerable danger in the use of it.

3250. (*Mr. Harrison.*) Allow me to point out to you the last paragraph in the last report from the Registrar General's office; do you agree in the opinion that that water is innocuous?—I understand that a quantity of sewage was poured in, and it was then oxidised and converted into simple compounds before the delivery of the water.

3251. It is simply by the process which it passes through in the river, and this being an analysis after it had passed through that process, the opinion is there expressed that it is innocuous, would you be of the same opinion?—I should think that it would be innocuous if it were completely converted into those compounds, the nitrates and nitrites of ammonia, if the quantity of sewage was not large in the first instance.

3252. That is the condition which is there reported as being that of the London water in the month of April last?—Yes, the sewage has been already converted, but then there is a constant danger that it will not be so converted. Those salts show previous contamination and a possible future contamination, therefore it is not that they themselves may be hurtful, but they show that matters which may be hurtful have passed in and may pass in again, and you cannot rely always upon the sewage matter being thus converted.

3253. (*Col. Harness.*) Do they not also, to a certain extent, lead you to infer what the remaining organic matter is, and may it not be of the same kind unconverted?—Yes, but I understand here that all the organic matter has been converted from day to day, and it might chance that one day it might be entirely converted and the next day not be entirely converted.

3254. (*Mr. Harrison.*) That appears to be only the result of a single day's experiment, the analysis of a particular day?—Yes.

3255. Still that is a report from Dr. Frankland, who is at the head of that department?—Precisely so.

Adjourned to Thursday next, at 11 o'clock.

Thursday, 16th May 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

N. Beardmore, Esq.

16 May 1867.

NATHANIEL BEARDMORE, Esq., examined.

3255. (*Chairman.*) You are a civil engineer, are you not?—Yes, I am a member of the Institute of Civil Engineers, and have had a good deal to do with water matters from my earliest youth. I have studied them as a matter of science as well as a matter of practical professional engagement.

3256. (*Mr. Harrison.*) You have also published a book which is well known as Mr. Beardmore's Tables on Hydraulics?—Yes, I published a book called "Tables" some years ago, then I published a more complete thing afterwards, and I hope to publish something better by and by; these things grow on. The object of that book was to give as much information as could be given on subjects similar to that which the Commission is now inquiring into.

3257. (*Chairman.*) Are you acquainted with the schemes and propositions that we have had before us for bringing water from the lake district, and also from Wales to London?—I am generally acquainted with them, but not in detail. I may say at once that they are matters much too large for me at all events to be able to judge. The works would be too heavy, and the nature of waterworks requiring you to pick the level, to a great extent renders it much more difficult to judge them than you would of a railway works where you can get a gradient a little steeper, and modify your works accordingly.

3258. Are you acquainted with the present sources of water supply to the metropolis?—Very well acquainted with them.

3259. Are you sufficiently well acquainted to be able to give a very confident opinion upon that subject?—Yes, I know a good deal about it, and could give a very fair opinion, so far as I am able, on the present sources.

3260. You are acquainted, are you not, with the Thames basin?—Yes, I am acquainted with the Thames basin, and also the river Lea basin. Perhaps I may be allowed to state that about 18 years since I became connected with the trustees of the river Lea, from whence, at that time, a supply of two-thirds of London was taken. There was then a great demand for an increase of water, and the quantity which the two companies drawing water from the Lea could take was very much limited. Owing to mills and other rights they had been very much checked. At that time they had been looked upon as taking, as it were, a little drop out of the Lea by favour, but in the course of years arrangements were made by which finally the whole of the valley practically was sold to the two companies. I felt then, what I have expressed with regard to the Welsh scheme, that really we were very much in the dark as to the volume of water that those streams gave. It is true Mr. Telford, and then Mr. Rennie, had gauges taken of the Lea once or twice, but it was evident that the volume of water was perpetually changing, and I established a system of gauging the river from day to day, and now I have carried it on 18 years, and by carefully observing and collating the facts, and comparing other basins with it, and particularly the basin of the Thames, I am able to give you a tolerably near approximation to what the flow of the Thames is, and I am able to predict pretty well what it would be under the driest or the wettest state of the year.

3261. (*Sir J. Thwaites.*) I thought you stated that your observations applied to the river Lea and not to the Thames?—I have gauged the Thames occasionally to test it by the Lea, and they are both very similar districts in some respects; they have a very similar rainfall.

3262. At what point did you make your gaugings on the Thames?—I have gauged the Thames at various points, at Kingston, at Staines, at Maidenhead, and different points.

3263. Did you make a careful section of the river?—I have taken it by velocities, and sometimes by the weirs in different ways.

3264. Is it a safe test to take the weirs?—A very safe test for the time being, for what you can get it at the moment. It is no test of what the river is running by the year; but you can get a very fair test for the time, and in gauging I have been also in the habit of taking it by the sections and by the velocities. There is no weir upon the Thames where you can take a day by day gauging, but I think Mr. Thornhill Harrison has laid down Mr. Simpson's height of the Thames at Kingston for a series of years, and I think he has got a very fair approximation to the flow from that, but still none of them are perfect; there is no perfect gauging of the Thames, over continuous periods.

3265. None of the weirs I think are in such a condition as really to permit of an accurate gauging being made?—No; I was very anxious some 13 years ago to get Mr. Bazalgette to begin to do so and he came out with me, but it was not practicable. Mr. Leach, the present engineer of the Upper Thames Conservancy, will I hope make one or two gauging-weirs. I have advised the Commissioners in the new works to make a weir somewhere up near Oxford and down below at Bell Weir, near Staines, and so to arrange these weirs that they can be gauged; my idea is that it may be well to put in the "Times" newspaper every week what the Thames is flowing. I could publish the volume of the Lee every week if I chose.

3266. Have you any tables to put in as evidence of the result of your gauging, or would you state it generally to the Commission?—I can put in a table which I have prepared showing the flow of the Lea and the estimated flow of the Thames for 18 years. I have lately prepared it, and I believe it to be very nearly correct.

The witness delivered in the following table:

Estimated Flow of Rivers Lea and Thames.

Mean Annual Flow, 1850 to 1866, including the Water Companies Supply.

	River Lea at Feilde's Weir. Drainage area, 420 square miles.				River Thames at Kingston. Drainage area, 3,670 square miles.

	5,010	44·9	·90	8·9	45,090	404·1	·95	9·68	10·21

3267. (*Col. Harness.*) Can you show it relatively with the rainfall of the same periods?—Of course I have put upon the table the rainfall of the same periods, but we are rather at a loss with regard to the Thames for a true estimate of the rainfall, just as you are at the head of the Severn, from what I understand. It is a very curious thing that there are no records of rainfall at the proper head of the Thames; that is to say, on the hills round at the back of Swindon and Cirencester, and so on, for a series of years; but I have had lately given me by Mr. Harrison the record of a rain gauge kept at Cirencester, and it shows what one might have predicted, that there is very considerably more rainfall at the head of the Thames than there is at Oxford. Oxford I believe, generally speaking, among those studying the subject, has been the standard: the rainfall is registered at the Radcliffe observatory.

3268. Does the height at that point offer a large face to the west?—No. The rainfall at Cirencester is not such as you would speak of with regard to mountains; it merely has some two or three or four inches a year more rain than Oxford, but this increase is a very important element in the perennial flow of a river like the Thames. During the last three months we have had decidedly heavier rains on the hills at the head of the Thames; these get into the oolite and give a very valuable flow of water during the time when it is important that the Thames should be full; that is to say, in the hot weather. If you have a good full spring rain, it is the character of all those rivers from chalk and oolite to give good volume through every kind of weather to the end of August, and that is a very important point to be considered.

3269. (*Chairman.*) Have you been able at all to determine what quantity of water could be supplied to London from the Thames basin, setting on one side the question of pollution, and speaking of it merely as to quantity over and above what is obtained at present?—The whole volume of water in the Thames during the minimum month of dry years may be taken at about 380,000,000 gallons per diem above Kingston—that is quite the minimum.

3270. (*Sir J. Thwaites.*) Is that for any given year, or is it the average?—The mean of the four months of June, July, August, and September, for 1864 and 1865, was only a little above 380,000,000 gallons per diem.

3271. What was the minimum?—The absolute minimum I do not know, but I should say it was not much lower than that. Those years were extremely dry years, according to my calculations. I have no year at all so low as those two years; 1854 should have been a low year, but there was an enormous volume of water the year before, and therefore the Thames flowed during the summer a very fair volume; 1855 fell down as low during the four months as 490,000,000 gallons, but it would have been lower had it not been for the immense supply of the year 1853; 1864, being a very dry year, had also the not high year of 1863 before it, and therefore the water fell off; 1863 was not at all a wet year, therefore 1864, being a very dry year, was low, and the drought ran into 1865.

3272. Has your observation enabled you to determine how many months of storing capacity those districts of chalk and other formations possess; that is to say, how many months is necessary to exhaust the storing capacity of that district?—That is just the point which I was going to answer. I have been searching for a law applicable to that for a very long time, and it is only within these last three weeks that I thought I had discovered this decided law; viz., that if you have a year of very low rainfall, with a hot summer, the chalk springs will gradually fail, and if there should be no October rains it will fall down almost to a minimum in November, but the absolute minimum is felt in the September of the following year, so that the storing power of the chalk is at least 16 months, because July is almost always a full month with chalk springs; for instance, the minimum in 1864 was only reached on the Lea in the September of that year, but the absolute minimum came in September 1865. In every dry year that we have had September has been the minimum month of that year, but the absolute minimum of the flow has been the September following. And the way in which it acts is this: The springs are running a constant and diminishing volume, because the rain of the year before and

the winter before has not been sufficient to replenish them; they are, therefore, absolutely diminishing. Then when you have got to the September of a dry year the winter rains following have not time to get down to the lower beds of the chalk, and although they have an effect in increasing the land springs, and keep the volume of the river up during the winter, and even during the summer months, yet the draining out of the lower springs developes itself at least in the September following a dry year. That is a rule; at least it is so nearly the rule that it has happened three times in 18 years on the river Lea.

3273. Then what makes you sceptical as to the correctness of that rule?—I am not sceptical, except merely that I am sceptical about anything with regard to rainfall and volume without even a longer series of years than we have had.

3274. You stated just now that you thought that you had discovered an unerring law with regard to the rainfall, the absorbing power of the chalk, and the time that that chalk would be discharging that which it had absorbed; have any circumstances led you to doubt the correctness of that law?—Nothing has led me to doubt it. It is only when I get an immense mass of figures collated before me that I can discover it; I feel perfectly confident about it. We had a general impression upon the Lea Valley that it was so some time ago, but I had not got the proof of it.

3275. (*Mr. Prestwich.*) Those deductions you draw from your observations on the Lea?—Yes.

3276. Where the conditions were very favourable, having a basin of only one geological formation?—Yes.

3277. Where in the Lea Valley were your observations taken?—At Broxbourne, at the junction of the Stort, and by gauging the flow off an area of 420 square miles.

3278. (*Sir J. Thwaites.*) Can you state when this chalk and other formations have discharged all the water, how many months or how many inches of rain would be necessary to re-fill that basin?—That I cannot tell except by inference, because after about a week's heavy rain in October the land springs and the upper chalk springs begin to fill and you get a mixture of the water; you get a large volume and it is impossible to tell the difference.

3279. But the water which would find its way to the lower bed of chalk would begin to flow would it not?—That we cannot tell, because we cannot gauge any one chalk spring, we only know that in dry years the higher chalk springs in the valley cease to flow, and that the lower springs do not vary in their volume to anything approaching the same extent.

3280. But you know the outlets from the various levels, and if they are all found running you have a right, have you not, to assume that the basin is pretty full all the way up?—Yes, perhaps after the October rains the upper chalk springs will begin to flow again. There is a very large spring at Woolmer park, for instance, that falls off in a dry year, and after about a month's heavy rain it begins to flow again very copiously.

3281. Can you state to the Commission the average rainfall within the Thames basin?—The average rainfall in the Oxford part of the Thames basin from 1850 to 1866 is 26·02 inches in the paper which I will put in, but I do not think that that is the average rainfall of the district. Oxford is only about 180 feet above the sea and a great many of the Thames hills are from 300 to 400 feet, and there is a most decided increase of rainfall as you get up.

3282. (*Mr. Harrison.*) What would you calculate rainfall at, taking the average of the Thames basin?—I doubt that as a whole, considering its more easterly position, any more rain falls in the Thames valley east of the parallel of Oxford than 26 inches. In some parts about Cobham there is decidedly less than 26 inches, but west of that parallel I should think that there are from three to four inches more rainfall, taking it over the whole surface.

3283. (*Sir J. Thwaites.*) Have you calculated the amount of rainfall in the area and compared it with your gaugings of the quantity of water flowing down the Thames in any period, so as to ascertain how many inches of rainfall actually flows off?—I have calculated it, and you will see that on this table I calculated that on the average of years about 8 inches flow off the Thames; but in the year 1859 there was only about 4·82 flowed off, and in 1864 there was only about 4·63 flowed off.

3284. Was 1858 a dry year?—Yes, but according to my calculations 1859 had the lowest flow. It may be interesting to know that the mean volume for this year is about 700,000,000 gallons flowing down the Thames at Kingston; the mean flow of 1858 I compute to have been about 850,000,000 gallons per diem.

3285. How do you account for the very small result of 4 inches for example in 1858 and 8 inches in the other years during an average rainfall of 26 inches. How do you get rid of the remainder; is it by evaporation, or by what?—By evaporation and absorption.

3286. That which is absorbed would naturally flow off, would it not?—No, it evaporates.

3287. If it be absorbed it would not evaporate?—It would be absorbed into plants. What I call flowing off is combining the whole of what goes into the surface and so into the chalk and into the springs, and absorption and evaporation in that sense is what the plants take up and what evaporates. There is an enormous quantity taken up by grass and plants during this time of the year. We know it practically because the first inch of rain in October after an ordinary dry year gives no water at all. Those valleys take no notice of the first inch of rain; it all goes into the thirsty plants and the soil.

3288. You have 26 inches to account for; that seems a very large amount of rainfall, does it not?—It is 26 inches if you reckon the average of years.

3289. (*Mr. Harrison.*) In a particularly dry season the reservoirs in the chalk become to a great extent exhausted, then they require to be filled again, and they are filled again; that would take in itself in that particular year a very large quantity of rainfall that year if it comes when the reservoirs have been exhausted?—Quite so, and I think I may say that in all those cases nature provides for herself. If you have a tremendously hot summer the ground cracks and thunderstorms come and the rain goes right into those deep cracks and replenishes the springs at once; I am clearly of that opinion. In 1864 I saw that practically myself. Cracks were formed all over the country; the first rains went right into them and they really were not lost; nature replenishes herself in that way. I think that, perhaps, part of the theory of springs, particularly in hot countries, is that the rain goes right into the cracks and fills them up; it is by this process that springs in India or such countries as Judea are fed, where the ground is baked and you have practically only four months rain. Of course the four months rain would have run away altogether if it were not that those cracks take the fall of rain and so feed the lower springs.

3290. (*Sir J. Thwaites.*) Of course your attention has been directed to the plan proposed by Mr. Bateman and also that proposed by Messrs. Hemans and Hassard. With regard to the rainfall to be obtained from the area described by Mr. Bateman, have you seen his calculation?—Yes.

3291. Do you concur in the net result which Mr. Bateman anticipates from that area?—With the little knowledge that I have of the matter I should exercise a sound prudence in declining to give an opinion, excepting in this way. The opinion that I am going to give has been given when I knew much less of these things. As much as 18 years ago I expressed the opinion to a very eminent engineer that I am now going to give. There is no amount of rainfall which, in a course of years, may not be exceeded, and, in this climate, there is hardly any amount of drought that may not be exceeded also, and I feel certain that no storing scheme is absolutely perfect. The area

N. Beardmore, Esq.

16 May 1867.

should be very large if it has to supply a large quantity of water, because you cannot, in this climate, avoid a couple of dry years coming together.

3292. Are you of opinion that the the mean rainfall would be a hazardous basis for a scheme of this kind?—Certainly, in the way it is applied, it is no basis on which to judge. If you wish for a real conclusion, you must gauge the streams, and keep rain gauges all over the country for some years.

3293. Assuming that the rainfall in the district has been thoroughly gauged, and that you have, therefore, no doubt as to the amount of rainfall, would you take the minimum rainfall as the basis of your calculation, or the mean?—Decidedly not the mean; but taking the minimum must be a little governed by the facts; for instance, if you had a very large amount of reservoirs, and had one very dry year, such as I am told occurs in those places sometimes, if you happened to have in the November previous a heavy rainfall, although the previous year may not be a very heavy year, you may catch enough to tide you over an absolute minimum year. It must be a matter of gauging the streams, and of calculations from those gaugings, as compared with the rainfall; but applying the general knowledge of these subjects which one has, I should say that you must not apply the figures of the rainfall in districts with a westerly aspect, or at the head of valleys trending towards the sea on the west, to ascertain the probable rainfall on easterly slopes. It is true that a very large amount of rain does go over some mountain summits, but, as a general rule, mountains are an absolute bar to the progress of the rain towards the interior. That is to be seen at Bombay in a very marked manner. A man could walk in a day from a district of 100 inches of rain into a district of 18. In the Himalayah mountains there is no doubt that the western face has an immense rainfall, but the interior of Thibet has none at all, or scarcely any; and those laws prevail in the small mountains and hills even in these districts of moderate rainfall.

3294. Assuming that careful gaugings have been taken for 20 years, and, taking the minimum fall during those 20 years, do you think that that would be a sound basis for the calculation and arrangement of a general scheme of water supply, giving of course, as every prudent engineer would, increased capacity to his reservoirs and all his works to meet cases of contingency?—Yes, if you rely upon the minimum falling over any given district. Perhaps a better instance cannot be quoted than the Liverpool case. In the year before last there was a scarcity of water there, and no one denies that the district is not a most prolific source of water, but they suffered there from drought. It has been said that they suffered from want of store reservoirs, but, in my opinion, it is quite a mistake; they suffered from one of those periodic droughts.

3295. But they did not take the minimum fall in that case, they took the mean of three dry years for the size of the reservoirs?—Yes, not the mean rainfall of these years, otherwise it would have required more than three or four times the amount of reservoir.

3296. (*Chairman.*) To go back to Kingston, and the daily flow there, which you say is 380,000,000 gallons, how much of that is now taken by the existing companies?—About 50,000,000.

3297. That leaves about 300,000,000 as the minimum going down the Thames?—It would leave the present minimum surplus falling over Teddington about 330,000,000, but the river is supplemented afterwards to the extent of some 60,000,000 to 80,000,000 between that point and Vauxhall Bridge.

3298. (*Sir J. Thwaites.*) Above the point where the water supply is taken there is no increase, is there, to the 380,000,000?—No, but after the water companies have taken their supply the Thames is again supplemented.

3299. With reference to Mr. Bateman's plan, and the gathering ground, you have stated that you have not sufficiently examined it to give a confident opinion as to the amount of water that may find its way into the several rivers?—No, I think I could not judge of that without keeping gauges and gauging the streams.

3300. And would you give the same answer with regard to Mr. Hemans's scheme for taking water from the Lake district?—I have not looked into Mr. Hemans's scheme sufficiently to give an answer, excepting generally that there is no doubt, I think, that the Lake district is more fertile of rain than the head of the Severn; taking area for area there is more water from the Lake district than from the Severn, unless you could get out to the western flank of Plynlimmon and Cader Idris; the amount of water that falls on the western face of those mountains is immense.

3301. But there would be an engineering difficulty about that?—Yes.

3302. Speaking as an engineer generally upon this question, and apart from the question of cost, are you of opinion that a sufficient supply of pure water to London might be obtained from the source pointed out by Mr. Bateman or by Mr. Hemans? I am not asking you as to the expediency, or as to the cost, but whether, as an engineer, you are prepared to state that a sufficient supply for the metropolis, present and future, could be obtained from either the one source or the other, say up to 300,000,000 gallons?—I should say that it is impracticable, having regard to the expense of the works.

3303. Do you mean by impracticable that the water could not be collected and stored, or do you mean that they could not construct the works to convey it to the metropolis?—I mean that to convey 300,000,000 gallons to the metropolis, to collect it, to store it, and to be sure of having the water, would be a very doubtful matter in its effect upon the quality of the water, and the expense would be so great that it would be beyond the means of any company; 300,000,000 gallons is a very large quantity to carry.

3304. What sized river would be necessary, in order to give a fall of 12 inches to the mile?—I understand, from Mr. Bateman's statement, that he reckons on a river 30 feet wide and 10 feet deep.

3305. But that is not with a 12-inch fall?—No, you cannot work a 12-inch fall. It would just be like what was the case in the Ganges canal, where there was a failure in carrying the water, from their fancying that they could work that amount of fall. You must not let water in that volume go along at such a speed. It is true that you may want a fall of a foot per mile, because you may and will have to pass wide valleys and ravines, which it would be beyond the power of man to cross in any other way than by pipes.

3306. You think that any fall beyond 6 inches would tear up the canal?—Yes. Practically you could not work even at 6 inches. You would require to have sluices at intervals for maintaining the level of the water. An average fall of a foot per mile I think is a very fair estimate, because you would concentrate your fall at places where you would have to put pipes across the ravines; I have no hesitation in saying that it would be quite impracticable to carry out any scheme without passing the valleys by pipes.

3307. With proper precaution is there any engineering difficulty in bringing 300,000,000 gallons of water to London?—No engineering difficulty beyond the cost. If you could insure rock tunnels all the way as they have at Glasgow you could race down the water at a velocity which should be quite a foot in a mile.

3308. But they have not rock tunnel all the way at Glasgow?—They have got a very large quantity of rock tunnel at Glasgow, and they can lead the water away with a very small aperture, but you could not do it through a great portion of the proposed district. You must make a canal which should carry the water along at a reasonable rate, and consequently you must have a larger canal with a smaller fall.

3309. What do you think would be a safe fall in a canal constructed as a canal of that description would be, lined with rubble or concrete?—I should think a

maximum of 6 inches, but I should be quite disposed to take credit for a foot to help me over difficulties. In many places in laying out the line you would require to have direct drops in your level.

3310. Of course, if you diminish your fall you must increase the size of your channel?—Yes, and as a matter of convenience and economy, I think it would be desirable to do so. You must not let 300,000,000 gallons of water get the master of you.

3311. (*Col. Harness.*) What velocity of current do you think would be allowable with a lined channel?—I think generally you must reckon it at two miles an hour, say between a mile and a quarter and two miles an hour. I think it would practically work out to that.

3312. (*Mr. Harrison.*) You have given a good deal of attention to the river Lea of which you are the engineer. Is the quantity supplied from that basin now nearly all taken up by the water companies?—In the year 1864 and September 1865 the river Lea volume was reached, but I must state that they had practically very little reservoir. The Lea must be treated with the reservoir system, and if you want a very largely increased volume down the Thames it must be the same.

3313. Supposing that additional reservoirs were made in the Lea, could the actual quantity now taken from the Lea by the water companies be much enlarged?—The minimum quantity taken by the companies is somewhat under 40,000,000 gallons, and the minimum flow of September 1864 and 1865 was somewhere about the same; and reservoirs, within practicable and reasonable limits of expense, can be made so as to store the winter spring water and deliver about 70,000,000 gallons.

3314. You think that the Lea itself would be capable of increasing the present supply from 40,000,000 up to 70,000,000 gallons?—From 40,000,000 gallons, as the minimum, up to 70,000,000 gallons; but there are many years when the river Lea gives 70,000,000 gallons right through the year. In fact, the river Lea, out of 18 years, in 1859 dropped to a mean of 70,000,000 gallons, and in 1864 it dropped to a mean of 61,000,000 gallons; but we could do a great deal more than 70,000,000 gallons on the Lea if the water from the Lea districts were supplemented from the Thames during very exceptional periods, because, generally speaking, our volume is up to about 90,000,000 gallons. We could give 90,000,000 gallons per diem throughout the year from the Lea valley as a general rule, with the aid of reservoirs.

3315. Taking now the basin of the Thames, you have stated that 380,000,000 gallons is the average of dry seasons over three months above Kingston, do you know whether the quantity at Teddington lock has ever been as low per day as 305,000,000 gallons accurately gauged?—No; I gauged it myself in July 1864, and Mr. Simpson gauged it off and on for a month in the same year, and we make it the same figure almost.

3316. What is that figure?—380,000,000. I have not got anything below.

3317. Is that at Kingston?—At Teddington.

3318. But do you take it above or below the water supply?—Whatever I speak of includes what the companies take.

3319. I am referring to that which is left after the water companies have taken their supply?—I think it is possible it may fall to 305,000,000 gallons on exceptional occasions, because at the time the gaugings were made the companies might have been pumping hard, or taking in an extra quantity for the next day.

3320. Or the mills may have been using the water?—Yes, in the dry time, in the upper district, every miller shuts in the water, particularly on Sunday. I should say that Tuesdays or Wednesdays water at Teddington, in very dry weather, would be a great deal affected by the millers in the upper streams shutting the water in. Up the Reading river and all the upper rivers, and up the Colne, every miller opens his sluices on Saturday night at 12 o'clock to wash out (as he says) his weeds and mud, if he can, and on Sunday afternoon he shuts in a store until he begins working on the Monday morning, and that amount of storage, although small in each mill, becomes quite a large quantity in the aggregate, and is very much felt; but the river runs the more from this in the other days in the week.

3321. Looking to the whole valley of the Thames above Kingston, do you think it quite practicable, by the provision of storage reservoirs for the flood waters, to take a much larger quantity from the Thames basin without any injury to the river below Teddington?—Yes, and not only without injury, but with very great advantage. Owing to the operation of the millers shutting in, and the flushes, and so on, the river is unequal. Even if you could add as little as 100,000,000 gallons a day to the river by reservoirs, it would very materially improve the character of the flow.

3322. Supposing that it were proposed, in addition to the 100,000,000 gallons which the water companies have power under existing Acts, to take an additional 100,000,000, do you believe that by proper arrangements and storage reservoirs that 200,000,000 gallons might be taken without injury to the river?—Yes, and even almost with advantage. You can store spring water above Oxford, and you may make a reservoir there for about 700,000*l.* to 800,000*l.* that should secure an additional flow during the summer months of 100,000,000 gallons a day. In round numbers, I think you might manage, for an expenditure of something like 800,000*l.*, to secure that the river at Kingston should never be less than 500,000,000 gallons a day, that is of course including what the water companies might take. When the river Thames is flowing 500,000,000 gallons a day, it is a fine body of water,—a fine grey deep-coloured water, and not weedy, but when the river flows down at the minimum, and it is the very hottest weather, of course the weeds are busy in growing, and the river has a weedy character which it would be very desirable to get rid of. But a reservoir on these rivers must not be looked on as a reservoir in the sense of a mountain reservoir. It would not be made to store flood water in the ordinary sense, but flood spring water. I have seen the river Thames above Oxford, and I gauged it twice this year at a point where a reservoir might be made, the one occasion being within two days of the melting of snow and a heavy flood, and the other being within eight days, and the water was clear in both cases, but in the latter case it was the clearest water I ever saw in a river in my life. The river was in flood; the whole of the marshes of the upper Thames were under water, and yet the water was absolutely pure. There was then flowing sufficient to have filled the reservoir in about a month with the finest water I ever saw in my life, without a mixture or a cloud of any kind whatsoever. It was remarkable water, and that was at Newbridge, above Oxford, on the Oxford clay. I was not previously very well acquainted with the river in flood time up there, and I had the river analysed for the purpose of seeing the nature of the water, and I was surprised at the small amount of clay that there was in the water. (*The witness produced a map of the basin of the Thames, and explained it to the Commission.*) The river drains the oolite hills in Gloucestershire, and the district is almost as sparse of population as any in England.

3323. (*Chairman.*) What was the analysis of the water?—It was the usual analysis of hard chalk water.

3324. What was the degree of hardness?—14°.

3325. What was the quantity of organic matter?—Scarcely any. If the Commission will allow me I will hand in the following analysis:—

W. Beardmore, Esq.

16 May 1867.

CHEMICAL EXAMINATION OF THAMES WATER when in flood, taken near Oxford, by Mr. Dugald Campbell, analytical chemist, of Quality Court, Chancery Lane.

Bottle marked "Specimen of the Thames at Botley "Bridge, Oxford, near Great Western Railway Station, "taken at 11·45 A.M., March 22, 1867." (High Flood.)

This water, when viewed in bulk, has a slight yellow tinge, and had no unpleasant taste or odour.

The total solid contents per gallon were 20·40 grains; consisting of—

Mineral matter - - - - -	16·20	"
Volatilized matter by carbonization	4·20	"
Oxidizable organic matter contained in the 4·20 grains volatilized matter	1·28	"

Degrees of hardness 10·5°.

Specimen marked "12 noon, April 5, 1867. Thames "water taken at New Bridge, about six miles from "Abingdon, on the Upper Thames (470 square miles "drainage), volume about 40,000 cubic feet per minute, "10 days after the top of the great flood of March; water "still over the marshes, but now of a beautiful grey colour "and purity. N.B."

This water when viewed in bulk had a very slight yellow tinge, and had no unpleasant taste or odour.

The total solid contents per gallon were 21·80 grains; consisting of—

Mineral matter - - - - -	21·20	"
Volatilized matter by carbonization	0·60	"
Oxidizable organic matter contained in 0·60 grains of volatilized matter	0·252	"

Degrees of hardness 14·5°.

3326. (*Sir B. Phillips.*) What amount of water do you consider necessary per head per diem?—I do not think that you can give a liberal supply, taking in the chances of waste, under 25 gallons per head per diem, excluding trade and public supplies.

3327. Including those, what should you say?—I do not think you will ever hope to do it with less than 35 gallons, the waste is so enormous.

3328. Taking the present population of London at 3,500,000, and the prospective population within the next 20 years at 5,000,000, what is your opinion as to the supply of London from the present sources, from the Thames and the Lea?—I think with such a reservoir as is shown on the map above Oxford, and a moderate reservoir on the Lea, you may take 300,000,000 gallons from the joint sources, and still leave the Thames with its minimum flow below Teddington the same as at present.

3329. What is your opinion as to the quality of the water supplied from those sources for the uses of the public generally for sanitary and domestic purposes?—I think that with proper arrangement of reservoirs the quality may be faultless, always excepting the carbonate of lime, which I regret to see published every week as so many grains of impurity, being merely a solution of pure chalk in the water. It is called in the papers impurity, but setting aside that carbonate of lime you will never get a purer water. In fact the new river is as pure as Loch Katrine now very generally, and with reasonable arrangements you may have the water still purer.

3330. Then you think that 300,000,000 gallons per day could be supplied, and that if the impurities which now pass into the water in the form of sewage and other impurities could be kept from the river and from the tributaries, we should have sufficient in quantity and as good in quality as we could desire?—A perfect water, setting aside what the public are now calling the impurity of 16 grains of chalk per gallon, which, in my opinion, is a great protective to the quality of the water; it is a guard against other things, if you exclude that you are always liable to have a solution of other substances. But in taking supplies from chalk rivers you ought not to take the water during heavy floods. It would be a great improvement to the supply of London if the companies were not obliged to take the water during the worst of the flood. No river is without impurities when the first flush of heavy rain comes, for instance the rains at the latter end of October and the January rains, but especially those at the latter end of October when the water flushes down a good deal of mud and dirt which should not be taken. In that respect the supply might be improved. On the Lea practically they have for years arranged to pass the water by in flood time. The East London Water Company have made during the last five years very large reservoirs partly with that object, so that the sluices should be shut down and the river let to slip by when it is foul, and then they take their water out of the reservoir. The New River Company have done the same for a number of years. They made 30 or 40 years ago reservoirs at Newington for the same object and also at Cheshunt, so that they shut the gates down when the river is in high flood and I think that in that respect the present draught of the companies might be improved.

3331. (*Chairman.*) You have stated that the quantity from the Thames basin and from the river Lea would be ample to supply the present and prospective wants of the metropolis, and also that the quality of the water might be as good as anybody could desire; setting aside the impurity of the chalk, which you do not consider an impurity, and excluding sewage and other impurities from the water, how would you propose to exclude the sewage and other impurities from the water?—By the new arrangement legislated for last year, by which the large towns are compelled to deal with their sewage themselves within three years, and I think within two years of the present time the large towns have to divert the sewage and distribute it over land. I do not see any other way of doing it.

3332. What sized towns do you refer to?—All towns with above 3,000 inhabitants, or in fact all towns that choose to have pipe drainage. Pipe drainage is an enemy to rivers. If you leave a town on the ancient system of cesspools, and they deal with their sewage in that way, practically nothing comes into the river except just during a short period of the first flush of heavy rain, and that is why I think that no company should take water from the river during the worst of the flood, when a great deal of filth is washed out.

3333. Cesspool draining is not considered a good system of drainage for a town, is it?—That is another thing; but if they go into pipe drainage, they ought to deal with it themselves.

3334. Is not the opinion of the present day against the system of cesspool drainage?—Yes, certainly.

3335. Then we must assume that the towns will not have cesspool drainage, but will have pipe drainage if that is the best system, and in these enlightened times we may assume that that system will be followed, or ought to be?—Yes, and they ought to throw the sewage over the land. No doubt that is the best way and the only way; all the other ways at present known, unless you go to very great expense with regard to charcoal and so on, are not perfect.

3336. (*Sir B. Phillips.*) Have you considered at all what will be the probable cost of the increased supply from its present quantum to the 300,000,000 of which we have been speaking?—The mere making of reservoirs sufficient for increasing that amount from the Thames and the Lea, and adding reservoirs such as the companies might draw from, whilst the worst of the flood is passing by, would not exceed in all about 1,500,000*l.* Beyond that amount it is a mere question of so much more coals, more engines, and more pipes; but that part of the question is being met every day because the companies are adding more engines at this moment. The Chelsea Company have now just doubled their power, the Grand Junction Company has been going to double their power, and the East London Company is going to add one-third to its power this summer. They are now building the engines. All that is in process of operation at this moment. If you continue the system as at present carried out by the companies, they must go on increasing their pumping power and other means of

distributing water, for the demand is increasing every day.

3337. (*Chairman.*) Do I rightly understand you that the only impurity which you consider the water now coming to London is charged with, is the sewage of the towns in the neighbourhood of the district through which the water comes?—Yes, that is the only impurity beyond refuse from papermaking up the Thames which is now prohibited by law.

3338. If we could assume an impossibility for a moment that there were no town in the district through which the Thames comes to London, would you say that the water would be pure?—Yes, certainly, because in point of fact the rivers from those tertiary districts are composed nearly all of spring water, and the general flow during dry summer months is absolutely spring water; there are no surface runs at all.

3339. Would not agricultural operations affect the water?—Certainly not except in heavy rains, agricultural operations have never been found to affect this district except in heavy rains.

3340. Assuming that there were no towns, or what might be equivalent to it, every town providing for its own sewage, you would consider the water to be quite as pure as you would wish it?—Certainly, the water of these rivers is in fact, during dry weather, spring water, and if you wish to collect the greatest amount of spring water for supplying London you must go to the line of the rivers, there you have the maximum of spring water, the river beds are in fact springs. The feeders of the Thames from Goring to the Duchess of Sutherland's must consist of spring water, for the hills surrounding have no streams; you may go 10 miles at a stretch opposite Reading without a stream; everything is swallow country, and the water all goes down into the chalk and finally has its vent, as spring water, either in the bed of the river or close to it.

3341. (*Sir J. Thwaites.*) Are you referring to the district above Maidenhead?—Yes, from Maidenhead to Goring the Thames passes by a gap through the chalk hills, and the whole of the country is streamless, with the exception of one or two branch rivers which are also chalk rivers and a set of springs, and if you wish to devise a scheme to get the greatest amount of spring water for London, you ought to take the Thames on the line of its course and the Lee in the line of its course. The river Lee from Ware downwards for about six miles is one mass of chalk springs; the springs either flow out in the bed of the river or within 100 to 150 yards of the stream.

3342. (*Mr. Harrison.*) Your view would be, as I gather from what you have stated, to apply the same principle to the Thames that is already partially adopted in the case of the Lee and the New River; that is to say, to preserve as much as possible the spring water in reservoirs, and in times of flood pass the turbid waters off?—Yes.

3343. And adding to that the powers which under the Act passed last session were given to the Thames Conservancy Commissioners to compel all the towns to utilize their sewage instead of pouring it into the river, your belief is that the Thames valley would then supply a water which would be pure in every respect except that of hardness?—Yes.

3344. Have you given much attention to the difference between hard and soft water?—I have of course had a great deal under my notice. I was originally in my early life engineer to a waterworks company which took water from Dartmoor. It was perfectly soft water, and I certainly have a great opinion of soft water; I like soft water very much.

3345. Having a choice between hard and soft, you would not hesitate a moment as to which you would choose?—For general use certainly I should choose soft water; but with a mixed population, unless you bring water in enormous volume and waste it away greatly, I doubt whether chalk water would not keep better than soft water in cisterns, and so on; chalk is a preservative against the solution of other matters, there is no doubt about that.

3346. Have you given much attention to the question of constant service to towns?—I have had it under my notice a great deal, and in that respect I know a good deal about the subject.

3347. Taking the question of the existing system of tanks in different houses, even if a constant service were supplied, would you continue those tanks, or would you consider it necessary to abolish them, and to have the water direct from the pipes?—You must have cisterns. I do not see any possibility of dealing with the general humanity, as you may say, without them. If you have such waste as you have in the low districts in London no pipes can furnish water constantly and with high pressure. You cannot deal with it. If you have a fraudulent or a careless man in one house he is wasting water away, and of course he is diminishing the head of the person next door, that is the difficulty you have got—to protect everybody and to give an equal pressure.

3348. Then that goes at once to the question of constant supply?—Yes.

3349. At the present moment the system is for the companies to have their mains, and then they distribute the water in the particular district, shutting one or more service mains off at a time?—Yes, so as to check the waste. The East London Company, you are probably aware, do give a very large amount of constant supply now. They have given 25,000 houses a constant supply, but they do it by placing a small diaphragm with a pin-hole ferrule, as it is called, inserted in the serving pipe, so that if the cock is left open there can be but a certain amount wasted. By that means they protect the district, as it were; they are giving a constant supply on a very large scale indeed in that sense, but it is not the sense that you mean by constant. You mean a plan by which you shall open a tap, and have a spout of water whenever you like, but they give it by a very small diaphragm, varying from one-twelfth to one-thirtieth of an inch in diameter. Then they always require a cistern, so that if a party chooses to open the cistern and let the water run off he must wait for the water to dribble in again. At this moment I have the general advising and management of a small board of health town near London, and we profess to give a constant service, but it is perpetually breaking down; one wrong-doer opens a cock and there is the whole thing at an end, and we have perpetual difficulties, and now I am dividing the services. We pump under 170 feet pressure, and we are going to give the low district a separate service in consequence of the enormous waste. In that district instead of a cistern an application called a preventor was used, by which when the watercloset handle was drawn a given amount of water only could flow into the closet, but the precautions are always evaded. The parties have only got to open the cock gently and the water dribbles away, and the waste is immense. We do not know what to do to prevent it, it is a perpetual annoyance, and then the fact of a turncock going round and complaining to people is very annoying. I do not think Londoners would like to have a turncock perpetually coming in and saying you have got something wrong. In some cases under my management I had notices from them ordering me to mend the taps and things of that kind. Of course it was an expense, and I wish to have an alternative service; it appeared to be suitable to the particular district to put on a constant service, and we have had it in use for some years, but it requires very good fittings. With the pressure that is necessary you must have very strong fittings. In the district that I referred to at Enfield, I have reduced the pressure from 170 feet for the low district to about 35, and the landlords of the houses have already thanked us for doing it. They say they are delighted at it. The expense of keeping up the fittings was so great that they liked the low pressure better.

3350. (*Sir J. Thwaites.*) Are you aware of the system in operation at Glasgow and Hull, where they are under constant pressure?—I know that it is constant pressure in Glasgow, but Hull I am not acquainted with.

N. Beardmore, Esq.

16 May 1867.

3351. You are not aware that in Hull, where the system of constant pressure is in operation, instead of waste being the result a saving of 25 per cent. has been occasioned?—Yes, and there is a great saving in Cambridge, but the supervision in Cambridge and the quantity of water used is so small, that no one would stand it in London. The supervision is close, and they put overflows there which shall flow down on people's heads from over the door.

3352. What number of gallons per head per diem is the consumption in Cambridge?—I think it is as low as 20 or 22 gallons, but there are no manufactures carried on there.

3353. That would be almost sufficient, would it not, for any ordinary population?—Yes, quite; of course they can do it where they have very active managers.

3354. Do not you think that if they had such active managers in the East London district the same result would follow?—I cannot say. I think that Londoners would not like the kind of supervision which must be given with constant service.

3355. Do you mean that the London house proprietors would not like the commencement of the alteration, which would entail a certain amount of expenditure?—They would not.

3356. Supposing that your pipes and everything were adapted for a constant supply, with proper supervision, can you see any difficulty in that system being carried out in London?—It might be done with a thorough amount of supervision with the expense once started with, but I should doubt whether you would be better off.

3357. Has not the failure of the constant supply system in the metropolis resulted rather from the companies adopting the constant supply under a pressure beyond the resisting capacity of the pipes and the imperfect arrangement of taps by the householders, as well as the want of general supervision?—I could hardly form an opinion. The whole of the supply of London has been a growing thing, and you have a great deal of trade supplies distributed very much through the district in all directions. I can scarcely form an opinion about it; on the whole I never had cause to complain of the water myself when I lived in London.

3358. You have of course lived in respectable houses all your life, but taking it as a general sanitary question, are you of opinion that the health of the inhabitants would be promoted and sustained by the adoption of the system of constant supply as contrasted with the intermittent system which is now in use?—I cannot say that, because I think the real evil is the iniquitous state of the poorer class of houses. They have no sort of cistern at all, and if you made it absolutely requisite to have a very moderate amount of cistern, and proper arrangements for taking in the water, and could keep the people from stealing the apparatus, you would be as well supplied by the present system as by the constant system. At present, in the low parts of London, in the east of London, you cannot keep a tap on a pipe at all; everything goes. It is a very large district at the east end of London; and the supply is afforded practically merely by open service pipes, so that when the water is turned on there is a great deal of waste, because no one cares to keep proper taps on the pipes. If you could have a general law making the landlords of small properties responsible, binding them to keep proper conveniences, you would do it; but what are you to do? What are you to do with a district like Limehouse, where you cannot keep a tap?

3359. (*Sir. B. Phillips.*) You say that you cannot keep a tap there, how do you propose that the landlord should keep those things?—If the landlord was bound to keep the cistern in proper order, and if he saw to it every Monday morning, and told the tenants that if the tap went he would turn them out of their rooms to-morrow and would summon them, it might be managed, but it is a very difficult question, indeed, to know how to do it. It is a question entirely for the landlords, and not for the companies. The water companies have plenty of water, whether it be the constant or whether it be the intermittent system; there is plenty of water, but there are no conveniences for taking it. Just apply the case, for one moment, to the question of gas. Supposing it were said, you give us plenty of gas outside but we cannot see in this room, and you went into a house and found that they had provided no gas pipes, or rather had cut them all off, you would not find fault with the gas company. That is the case with the poorer districts in London, with regard to water. It is utterly impossible to keep anything in the shape of proper fittings for a habitable house.

3360. (*Chairman.*) I am afraid that would go against any supply of any sort?—Yes; that is the reason why I say that the difficulty is not one of constant supply, but a difficulty as regards the detail of distribution.

3361. (*Sir B. Phillips.*) Supposing that the difficulty could be overcome, would you then recommend a constant supply in preference to an intermittent one?—I would scarcely go so far as to recommend it, but I think a constant supply would be much easier of attainment. In order to have a constant supply you must have an even pressure, and if you have two or three wrongdoers in a small court who are drawing all the water out, where is the pressure? You cannot do it.

3362. (*Sir J. Thwaites.*) I suppose there would be no difficulty in having some mechanical arrangement for the purpose of watching the condition of the pressure in the pipe, whether it is being exhausted by wrong-doers, as you describe them, or discovering whether the things were in a satisfactory condition?—Not the slightest difficulty; you might put pressure gauges.

3363. I mean that some pressure gauge might be fixed in a court of 20 houses to determine the pressure, and if the pressure indicated something wrong the officer could just go in and see for himself?—Yes; you may have a pressure gauge fixed to a lamp post in every principal street, if you choose.

3364. If it were made a condition of the tenancy that those arrangements should not be interfered, it would very soon operate upon the tenants themselves, would it not, because if they found that unless they left those taps and things to work in their proper course they would have to leave their lodgings, that would soon tell upon that class of persons?—Yes. You are aware that the local authorities have now power to compel a landlord to do those things, but they never exercise that power.

3365. The great mischief is the faulty receptacles which the poor have for the purpose of storing their water, is it not?—Yes.

3366. And that invariably, in consequence of the absence of any sanitary knowledge, they will place the water just where it can be contaminated, that is to say, just where it can take up the gases which are generated either in privies or ash-heaps, or where any filth is deposited and decomposition is going on, and, of course, the result is fever in every form?—Yes, I think myself that the poorer districts of London would be very much improved in their water supply if there were public standcocks for the courts, where the people could run out and get their jugs full at all times, and be constantly supplied. There would be no doubt that the companies could do that with the greatest facility. The Carlisle and Nottingham supplies for courts and small rows of cottages are all done in that way; they give one or two standcocks to a row of houses; and they give no interior supply at all in these and many other towns, to certain classes of property.

3367. (*Sir B. Phillips.*) Would it not be a much safer principle to supply those small houses with standcocks?—Yes, if you had the power of levying a rate upon them. I take it that it is rather a financial question whether the landlord would not say that he would not pay the rates unless you put the water in the house. But in Carlisle, Lancaster, Notting-

ham, and many other towns, I believe that they pay the rate just the same. I happen myself to be the owner of some small property in Nottingham, and I pay the rate for every house although I have only a standcock in the centre of my court.

3368. Supposing standcocks were placed in the courts with a constant supply for the inhabitants of small tenements, as you say, the probabilities are that the landlord would say, "I will not pay the rate unless the supply is brought into the house;" but if the water were brought into the house and he had to pay the rates do not you think that that would be a great security for the supply in the house being better looked after?—Yes; but he has to pay the rates now.

3369. I understood you to say that if there were a constant supply in the court it would be a financial question, and the probabilities were that the landlord would not pay the rates for the houses because the water was not supplied in the houses?—Yes.

3370. Supposing a case like that were to arise and the landlord were to say, "I will not pay the rate because "the water is not brought into the house to supply the "inmates; bring the water into the house and then "I will pay the rate;" do not you think that in that case it would be a great guarantee that the landlord paying the water rate for the supply of the house would see that all the appliances were kept in good order?—The only guarantee would be in compelling the landlord to do it. Practically the landlord takes no notice of it. The waste goes on and he takes no heed of it; he looks for his rent and he pays the outgoings. If you made it compulsory in this way, that the company should be bound to find within a reasonable distance a standcock, and to maintain it at their own charge and charge the buildings with the rates, I think that there would be less waste, and practically a better supply for the people who would run for their water to this cock.

3371. Are you aware that during the recent cholera outbreak in the east of London some of the water companies supplied standcocks gratuitously to the poorer districts?—I believe they did so.

3372. Do you know what was the the effect of that?—I do not.

3373. Then really, in other words, if I understand you correctly, you object in one way to the constant supply, but you approve of it in another way; that is to say, you approve of the constant supply by standcocks in courts?—Yes. I say it in this way, that with a standcock in a court, for some half a dozen houses, under the open control of the company, there would be proper security against waste, but if you give the water to all the houses in the court there would be an immense deal of waste, and all the fittings would have to be multiplied. I think that if the landlord were relieved of the expense of all those fittings, and had a standcock instead, he would be very thankful, and the people would then have the water to go to. But there would still be the question of waterclosets left.

3374. But I still understand you to recommend standcocks for the supply of those small courts?—Certainly. I think that it would be a very great improvement if standcocks were placed in those low neighbourhoods.

3375. (*Chairman.*) You stated that if standcocks were placed in courts under the control of the company it would be an improvement. In what way do you mean that they would control them?—I think that the company would not be very much burdened, the standcocks having been once erected by the authorities, if they maintained them and just kept them tight; and they would have a very strong interest in doing that, and the company would hardly feel the expense of it. Speaking practically, the standcocks, which are merely those wooden things that are put into the plug, and that they use in times of frost, are always maintained by the company; but if the system were adopted permanently, there must be something better than those.

3376. There would, in that case, as Sir Benjamin Phillips observes, be a constant supply?—Yes.

3377. So that any person in the court could go and take the water from this standcock whenever he pleased?—Yes, he would lift the ball and turn the tap.

3378. Might he not leave it half open?—I think that it could be arranged by the ball in some way or other so that there need not be any waste in that way. And I think that, it being a public thing, the company would naturally look after it, because the expense would be very little.

3379. Supposing that those standcocks were put up in the courts, there would be no reason, would there, why there should not be also water supplied for the waterclosets?—No, not at all.

3380. Because, although there might be some waste in the supply to the watercloset, there would be less waste by taking the water from the standcock out in the house?—Precisely so. Of course you could not keep the waterclosets sweet without having a supply of water to them.

3381. You have stated that the quantity of water in the Thames basin is ample, and you have described the quality as good, save and except that impurity which you do not admit to be an impurity, have you gone into the medical question of the water, as to whether hard or soft water is better or worse for health?—Not otherwise than applying my own knowledge to things in general, and knowing that the majority of mankind drink hard water, and look for hard water. It is very remarkable how they avoid soft water for drinking.

3382. Are you speaking now of water of from 12 to 14 degrees of hardness?—Yes. It is very remarkable how mankind always look for hard water to drink. I recollect some years ago being engaged in some mountains in Spain, where we had soft water running by, and the inhabitants would never give you that water; they would refuse to give it you, and that struck me very much. They would say that it would give you the colic. That is the general impression, and it is so everywhere. All mankind go to hard waters for drinking, as a general rule. In my own house in the country we use very hard water, harder than any water that there is on the Lea valley. We use the hard upper water of the valley coming out of the gravel, and we enjoy very good health. Of course there is a water that transcends all water, and that is spring water from the granite. That is pure water, and absolutely soft, and it is the water that you go to drink at Malvern; the water dribbling out of the rock there is absolutely pure water. There is also a spring of it in Dartmoor, which I have often drunk with very great pleasure. It is absolutely pure water, and if you get it when fresh out of the ground is really charming water.

3383. Have you ever been in Scotland?—Yes, I have been in Scotland a great deal.

3384. What is the character of the waters in that country?—Some of them are wonderfully pure. Some of the waters flowing out of the slate rocks and the granite rocks are of that character, beautifully pure.

3385. Have you ever been up as high as Aberdeenshire?—I do not know Aberdeenshire very well, but I have been there.

3386. Would the water there be likely to be of that character?—It is chiefly soft water. There is some hard water in Aberdeenshire, but the soft water is exquisite water as a general rule. There is such an immense quantity of granitic drift in Scotland. Take the wide world, and go to Russia or to Germany, or through the whole length of France, and with very few exceptions you will drink the hardest water.

3387. What I gather from your evidence is, that although you would prefer soft water to hard water, if you could get it for ordinary cooking and domestic purposes, and possibly for washing and possibly manufactures, yet as regards health, judging from the circumstance that the bulk of mankind drink hard water, you would not care to get soft water for the

N. Beardmore, Esq.

16 May 1867.

metropolis on that account?—On that account I should not.

3388. (*Sir B. Phillips.*) Do you think, in one word, that the water supplied to the London public from its present source is prejudicial to the health of the metropolis. I am, of course, speaking of pure water divested of all its impurities?—Certainly not, I was a good deal in the infected district last year, in the east of London, and I think that the whole of the out cry was perfectly baseless, as regards the cholera having anything to do with the water supply.

3389. (*Chairman.*) Will you identify the particular district which you are now speaking of?—I mean the district where the cholera raged so intensely in the east of London.

3390. Do you consider that the prevalence of cholera in the east of London last year was not attributable to the supply of water in that district?—Certainly not.

3391. Will you kindly give us your reasons for coming to that conclusion?—First of all I drank some of the water myself at every opportunity, to try it, and I had a large number of labourers and navvies under me at the time in the worst district, and where the foulness of the Limehouse Cut was the greatest, and scarcely a man was free from an attack of diarrhœa, but I should doubt whether any one man drank the water at all except in the form of tea, and there was quite filth enough in the neighbourhood in the water of the Lea and in the defective drainage, and in the close habitations where the men lodged, to account for the attack of cholera. An accusation was made against the East London Company that they let in the water from a certain reservoir and mixed it with their district supply. I had under my own cognizance several families who drank nothing else but the water which furnished this very foul supply as alleged; they had young children and some of them delicate children, and yet they were more free from the attack of the disease than the general run of the neighbourhood. I attribute that to the fact that they were living out of the thick neighbourhood in open ventilated places, but those families were absolutely drinking and living upon that water, the children and all, and there never was a death amongst them. If the Commission wish to learn more of this subject perhaps I might suggest to them the name of the medical officer of health for the Limehouse district with whom I was in constant communication, because I was carrying on works that compelled me to keep the Limehouse Cut deodorized, and I saw him constantly. I found by accident a little time since that he published a report distinctly giving it as his opinion that the water had nothing to do with the outbreak of the cholera. The gentleman I refer to is Mr. Orton, the medical officer of Limehouse, a very intelligent man, and one that had the best opportunities of knowing. I very much fear that the cholera was caused by the use of bad pump water; there is no doubt about a large amount of pump water having been used. I think that in Jubilee Street, Mile End, it turned out that the houses that were attacked the worst were all using pump water fetched from a greengrocer in the street.

3392. (*Mr. Harrison.*) Has it not been found that a leakage was actually taking place into the reservoirs through the bottom from the river Lea?—No, it was suggested by a medical gentleman who went down that there might be a leakage.

3393. Is it not the fact that Captain Tyler has had those reservoirs emptied and discovered that that actually was taking place?—I did not know of it.

3394. I think you will find that it has been admitted to be the fact that into those reservoirs an actual leakage from the river was coming in at the bottom?—If Captain Tyler examined it of course he pumped it out, and then there may have been a leakage, but how could there have been a leakage when there was no pressure?

3395. If there is a connexion between the two, of course the effect may have been so?—But how can there be leakage with no pressure?

3396. The water of the Lea may at times have been higher than the water in the reservoir?—Yes. However, the abomination of the smells and the foul ditches were so great in the neighbourhood that it was enough to make anybody ill to go for a moment into any part of the district, particularly where the cholera actually broke out at Bow. No words that I could use could describe the abominable stench that came from a paper works there. The first of the number that was seized in that street at Bow worked in a low shed in Stratford, by the side of a ditch which came from a yard where they took all the foul matter from the London markets, and boiled it down for fat, and the foulness of the place and the closeness of it altogether was something beyond description. That was at Stratford. They were taking 30 tons of meat away from Leadenhall market at that time and boiling it down in a putrid state, and it infected the whole district, and the refuse went into a ditch which flowed by where those people who were first attacked worked.

3397. (*Mr. Prestwich.*) You have given us the gaugings of the Thames and the Lea, have you any gaugings of the Severn?—No. I calculated the flow of the Severn many years ago in the lower part, but I have no data with regard to the Upper Severn.

3398. You do not know what the flow of the Severn would be at Shrewsbury?—No, I do not.

3399. You gave us the mean daily fall for the period of four months of the driest years for the Thames and for the Lea; do the papers which you have put in give the mean fall for the entire year of the driest year?—Yes.

3400. (*Col. Harness.*) Do you consider that the large reservoir which you propose near Oxford would be sufficient alone to ensure a minimum supply of 500,000,000 gallons a day at Teddington?—Practically that reservoir alone would give very nearly that quantity.

3401. What capacity do you propose for that reservoir?—That reservoir would contain, I reckon, 100 days supply, at 100,000,000 gallons a day.

3402. Can you give us some idea of its surface and depth?—Such a reservoir would be nearly 2,500 acres in area.

3403. That is something under four miles, is it not?—Yes.

3404. And what depth would it have?—It would have not less than 16 feet of depth. I think it can be arranged to have more depth than that. Of course the surveys that I have made are only preliminary, and they could be improved upon a good deal.

3405. Does the site offer much facility for making it there?—Yes, it is a very good site indeed; it is steep on one side, and the other side would have to be embanked. It would be at Northmore, near Stanton-Harcourt, that fine old place that belonged to Lord Chancellor Harcourt. Why such a site as that would be selected is this: It is a great object to have depth to the reservoir, and the valley is so flat that it is quite difficult to get the depth, and I propose to make a tunnel down to Abingdon, so that you could put a dredger in at any time, and deepen the reservoir.

3406. In making the reservoir, on one side you would have a slope, would you not?—Yes.

3407. Would the whole of the remainder be embankment?—Yes.

3408. Then you would get a great length of embankment?—Yes, I should excavate about 12,000,000 cubic yards for the sake of getting depth.

3409. Is there a great depth of the Oxford clay there?—I do not know.

3410. Have you in your experience been able to find out whether there is any important amount of leakage in any of the large reservoirs that are made in that way?—The advantage of a reservoir in this site would be that there would be no leakage, on account of its being clay and its being excavated, and there would be no pressure to leak from, and I should

hope that a reservoir could be made there with a depth of 20 feet, and I think that it would be a success.

3411. Have you made any observations upon the leakages that take place in the large reservoirs that are in existence?—There have been some large reservoirs made where a very great amount of leakage has occurred under a heavy pressure, but no reservoir would be made in any of those valleys with that amount of pressure, such as 70 or 80 feet; that is a different kind of thing, of course. We know that there was some leakage at Rivington Pike, for instance, owing to water escaping through some old quarry workings, and thus creating an artificial spring; and they have had very great waste in some of the Bradford reservoirs, but no reservoirs in this district would be anything like approaching to that class; they would be more of an artificial character altogether, and with comparatively small pressure. When embankments exceed 50 feet in height the leakage is much more difficult to deal with than at lower pressures no matter what the soil may be.

3412. Are you aware of any facts which have been published with respect to the leakage of large reservoirs?—The French have published a good deal on that subject and on the loss of water, and they calculate it to a nicety in the head district of their Great Eastern Canal, but I do not think that anything has been published in English upon the subject.

3413. (*Mr. Harrison.*) Instead of excavating such a reservoir to a depth of 12 feet it would merely require you to bring your conduit into it, a mile or two further back, and you might then regulate it to such a depth as would balance the amount of your excavation and embankment?—Yes, that could be adjusted; I should hope to get a reservoir there for within 800,000*l.* and I should have 20 feet more water by proper dredging if you like below that. Of course a puddle gutter would be carried all round the reservoir so that you could dredge or do anything you like with the interior afterwards.

3414. (*Col. Harness.*) The water from that reservoir at Oxford would still pass by the bed of the Thames, would it not?—No, it would be passed throug a tunnel to Abingdon on account of the difficulty of drawing off. The bed of the river above Oxford is so excessively flat that you can scarcely do anything with it without making a tunnel through to Abingdon, and there you have the advantage of carrying the water sweeter and cooler down the main body of the river, and you avoid any impurity in passing Oxford. The stream is so flat there that you can never get a rapid stream, it would always be sluggish in the valley.

3415. You spoke of a large amount of springs which entered the streams both of the Lea and of the Thames between Goring and Maidenhead valley. Have you ever measured the accession received by those streams from the springs alone where no tributaries flow in?—I have attempted to do it by gauging the river above where it entered the chalk district, and also below. I have attempted to do that some years ago when the river was in a low volume, and I ascertained sufficient to prove what we almost knew; viz., that there was a great increase of water, but I have never calculated it out. It was a very large accession indeed, and I will just show it on the map (*producing a map and explaining it to the Commissioners.*)

3416. (*Sir J. Thwaites.*) Does that represent the whole of the Thames?—It does not represent the whole of the basin, but that nearest to the Thames. Mr. Prestwich perhaps will tell you better than I can, that beginning a few miles above Reading, and passing over the north of the Thames to the Colne, it is almost a streamless district of bare chalk, or covered by the Bagshot sands which absorb all the water. It is intersected by a very fertile chalk stream which flows up by High Wycombe, and also by a branch of the Colne, and I take it that from this area there is something like 300 square miles of absolutely pure water drainage. I do not think there is any water at all that is not spring water which flows out of it, except under very extraordinary circumstances.

3417. I understand that the place indicated by this colouring on the map would be an excellent site for a reservoir, and the area would be about four square miles. Can you give us any description of the surface occupation, whether it is valuable agricultural land, and whether there are houses or railways or anything that would interfere with the formation of a reservoir there, or if not, whether the purchase of that four square miles would be very expensive?—It is mostly drowned marsh land which gives a very good crop some years, but in some summers no crop at all, and there are scarcely any houses upon it.

3418. There is a village here (*pointing to the map*)?—Yes. Of course you would shut out the village. There are scarcely any houses, and the pressure of a reservoir like that would be *nil.* The ground would be excavated at least nine feet, the bank of that reservoir would not be above ground altogether more than 12 feet.

3419. Are those pasture lands?—They are very wet marsh lands, averaging 25*s.* to 30*s.* an acre; it is not rich land like the Thames valley below Oxford.

3420. (*Chairman.*) Does it carry any stock upon it?—They take hay off it and it carries stock.

3421. They would get more than 25*s.* an acre for that land, would they not?—I doubt if that land is worth more, because some years they lose their crop. In a wet summer they do not have any crop at all, there is a certain degree of risk withit; they get from 25*s.* to 35*s.* I should think for some of it; some of it is better than others, some of it lies a little higher.

3422. (*Mr. Prestwich.*) You stated that you had made some gaugings in the lower part of the Severn valley, how low down did you go?—I calculated it from a survey made by the Admiralty some years ago, but it was quite the lower part of it, after it had received its tributaries, and it would not be at all applicable to the subject of the present inquiry. Shrewsbury would be too low to gauge to give any idea of what you would really get, because you would not get enough rain; there is much more water in proportion to the area as you approach the mountains.

3423. But would not gaugings a little above Shrewsbury give the daily flow of water from the district described by Mr. Bateman?—I would rather go higher, because you would be gauging the water from a country having a lower rainfall. To give the fair amount of rainfall the gaugings should be further up, nearer the mountains.

3424. In the table which you have put in I see that you do give the mean daily flow for the driest year, and in the driest year, taking the Thames and the Lea together, you get a mean flow of 733,000,000 gallons, which would fairly represent the delivery of the Thames basin above London, including the valley of the Lea?—Yes.

3425. For the driest year; that is the year 1864?—Yes, and excluding the Wandle and some of the Colne (one branch of the Colne, if you recollect, comes away down to Brentford), and the Hogs Mill river also. This estimate also excludes the water-bearing districts of the North Kent Water Company, and the springs there are available to the population below Dartford and over the area drained by the Medway.

3426. You stated that you had arrived at a probable law with regard to the delivery springs in the chalk, that it took a period of about a year and a half for the surplus quantity stored in the chalk to be delivered?—Yes, finally drained out.

3427. How have you been able to separate the delivery of the following year in September from the rainfall of the previous winter?—You cannot, except by inference. We know that if a dry summer follows a dry summer the land springs cease, and there is comparatively no surface flow, and we know from general facts and the general appearance of the water that it is all chalk water, in fact all water from the low springs. There is no other water in such circumstances as this; it is a pure deep chalk water

N. Beardmore, Esq.

16 May 1867.

flowing in such years. At the end of September 1864 or 1865 there was no other water at all. The river Stort, which drains a clay country, came almost to nothing in that month in both those years. That river has comparatively little chalk water in it, and it came almost to nothing.

3428. Have you observed that, notwithstanding a heavy fall in the previous winter, when there has been a very dry year before that, the springs in the September following the rainy winter have nevertheless suffered from the dry season of the previous year?—Yes, the water has not got down to them.

3429. In many towns soft water has been of comparatively recent introduction, but are there any towns in which you have been able to observe the effects of the introduction of soft water after they had been accustomed to the use of hard water?—The strongest case at all that I can recollect is that of Glasgow. Glasgow was supplied with very hard water at one time, and when the river water was used, although softer, it was liable to be foul; the south side of the river about the year 1850 was supplied by a new company, called the Gorbals Company, bringing a very soft water. That company almost supplanted the old hard water company, and then followed Mr. Bateman's Loch Katrine scheme of supplying soft water, about five years ago, to the north side of the town. The final change was made then.

3430. Have you had any opportunity of noticing the effect produced by the change upon the health of the people?—No; I know of nothing about that point. I am only pointing out that fact in order that the Commission might have their own means of ascertaining the result, if they could. There is the fact that there was a change then from hard and inferior water to very soft water. I think, if I recollect rightly, the Glasgow water was at one time very hard. I think there were sulphates in it, as pumped from the lower basis of the coal measures under the Clyde.

3431. You stated that some years ago you had occasion to introduce the Dartmoor water to Plymouth?—I was engineer to the company, and we had soft water. I quite appreciate the value of soft water if you can keep it free of peat.

3432. You did not first introduce this soft water into Plymouth, did you?—No, there was soft water there before. The great evil, of course we know, in the case of soft water is peat, but that of course you are liable to even now; even the water of Glasgow, pure as it is, will sometimes have a brown colour. I had water brought up to me in the hotel at Glasgow last year which was excessively brown, as brown as the oak in the table before me.

3433. (*Sir J. Thwaites.*) That was from the peat?—Yes. In laying out a scheme for bringing water from the Severn you must reject the bog water streams, or else they will colour a vast quantity of good water; but that is a mere matter of detail. Londoners would not stand that colour.

3434. (*Chairman.*) But that brown colour would only be after floods?—There are in those mountain streams bog water streams that are always foul. You must shut them out of any scheme. You must turn them away. You ought never to let in any bog water stream.

3435. (*Mr. Harrison.*) You could almost always do that, could you not, in any case where it was necessary?—Yes.

3436. Did you ever see the London water a little coloured?—Yes. Of course, in both cases, you should shut out flood water and anything that is likely to foul water.

3437. (*Mr. Prestwich.*) Have you ever noticed the effect of soft water upon pipes, either of lead or of iron?—No, I have never had any practical experience myself of the matter; but you are aware that iron is much more difficult to keep from rusting in pipes holding soft water than in pipes holding hard water. There is no doubt about that. The way in which our pipes at Devonport used to foul with the peat and softness of the water was very extraordinary; sometimes when the water lay dead in them and there was not much change, at the end, perhaps, of 10 or 12 years we should have to take out a pipe almost filled with a mass of unctuous stuff, half peat and half iron, and the pipes were really very seriously eaten out by it. We know that chalk water is very advantageous for pipes in that respect; the chalk deposits in the pipes instead of eating them.

3438. Where would you propose to place the reservoirs on the Lea in order to regulate the flow of that river?—I think they should be, as a matter of convenience and economy, somewhere in the neighbourhood of Waltham Abbey, but to get a proper depth, you might make a reservoir on the Lea very well with 30 feet depth, by having a feeder from the river above so as to give the proper depth of water as described by Mr. Harrison in the case of the Thames. The Lea valley is bottomed by the London clay; it is about 18 or 20 feet through the gravel down to the clay, and in any reservoir in the Lea valley you would have to puddle down that depth. I would not attempt to put a reservoir above where the London clay is. The London clay is thrown up apparently by a fault running somewhere in the neighbourhood of Broxbourne. There the bottom of the valley is London clay, and you may make a reservoir to hold absolutely tight without any leakage at all with the pressure that you would give to the reservoir there, in fact the East London Company have done so. Mr. Greaves, the engineer of the East London Company, has of late made such reservoirs, by puddling through the drift gravel down to the London clay, and in one case he went down 28 feet to the London clay, just above Walthamstow; thus making his reservoir absolutely tight. In the upper part of the valley there is more difficulty in making reservoirs. I was concerned with the late Mr. Rendel some years since in devising reservoirs on the upper branches of the Lea; we did not know much about the quantity of water that would run off at that time, and from what I saw of the borings of the beds of the streams, and the flow of water from the ground, I should not be disposed to recommend very deep reservoirs to be formed by dams across the valleys. I do not think they would be thoroughly tight, unless you could find some special areas where there is clay, which is very difficult to get. The volume of spring water during the winter months is so enormous that with a reservoir situated low in the valley, you may get practically a store of spring water for use during the dry months of summer.

3439. Sufficient to ensure a delivery of how much?—I think you might ensure 70,000,000 gallons. The table will show of itself, that many years you can get a great deal more than 70,000,000 gallons out of the Lea without any reservoir at all, but even then the reservoir becomes of use, because in a full year the river is flooded very often, and at such times, for that season, the reservoir is of very great use. I have just taken out a little statement showing about the number of days in each year that the river Lea is turbid. That is a point which the French investigated a good deal when they were studying the question of what new supply of water they should give to Paris, and practically this table, which if the Commission will allow me I will put in, will tell you the number of days over 17 years in which the river Lea was turbid. The turbid periods in 1858 were only five, in 1860 there were 26 periods of turbid water, showing an enormous difference in different years. In those dry years, 1858 and 1859, it was pure grey water practically nearly throughout the two years, but of course the volume was greatly reduced. When I speak of grey water, I think perhaps gentlemen may have seen that peculiarity. You may always know whether water is merely loaded with carbonate of lime, and is perfectly pure as spring water, by its colour. You see that in the streams of the Jura mountains very strongly; wherever the water flows from limestone it is French grey, a greyish blue colour, it is unmistakeable, and in all chalk springs you see it.

With the permission of the Commission, I will hand in this table.

The witness delivered the following table:

River Lea at Feilde's Weir.

Drainage area, 420 square miles.

Statement showing the Number of Days and of Periods in each Year when the Water was turbid, from 1850 to 1866.

Years.	No. of Days.	No. of Periods.	Mean Duration of Turbidity.
1850	13	7	1·85
1851	32	10	3·20
1852	96	16	6·00
1853	125	18	6·94
1854	24	6	4·00
1855	22	6	3·66
1856	27	7	3·85
1857	28	12	2·53
1858	12	5	2·40
1859	22	6	3·66
1860	73	26	2·80
1861	37	11	3·36
1862	16	7	2·28
1863	12	5	2·40
1864	8	2	4·00
1865	22	9	2·44
1866	53	18	2·94

3440. (*Sir J. Thwaites.*) Have you any further observations to make which you think would be useful to the Commission?—I made some remarks in the paper which I sent in as to the expense of getting water into London by gravitation, and they are to this effect:—The engineering difficulties and expense will be very great for an entirely new distribution of water by gravitation from one centre, such as Stanmore, situate 10 miles from the outskirts of the nearest point of the metropolis, and upwards of 18 miles from the furthest present point to which the London water companies supply. The expense of re-arranging the distribution of water over the metropolis so as to obtain gravitation pressure equal to that at present given appears likely to exceed any estimate that has yet been given. Even supposing that the water companies are merged into one body, there can be no doubt that the present companies occupy areas (urban and suburban) which at any rate must be considered as six districts requiring independent mains from Stanmore; thus the New River district would require a pair of 36-inch mains, from 12 to 14 miles in length each; the East London district would require a line of 42-inch mains 14 miles in length, and another line of 18 miles of the same size; the immense area served by the Lambeth and Vauxhall Companies would require four lines of 42-inch mains, and a bridge over the Thames specially constructed for carrying the pipes into the southern districts. I estimate these arrangements for all the districts at about 2,000,000*l.* A distributary reservoir at Stanmore should hold at least 30 days supply, otherwise an accident on the line of conduit between Wales and London would leave the metropolis without water. Therefore the service reservoir should hold 4,000,000,000 of gallons, or 650,000,000 of cubic feet. This should be uniformly deep, to avoid growth of weeds and heating of the water. Such a work would not cost less than 800,000*l.* and probably nearer 1,200,000*l.*, considering that its position would demand that most of it must be excavated artificially. On these data the total cost of distribution in London would amount to about two and a half millions sterling. This estimate is exclusive of the Kent Waterworks district, the revenues of which Mr. Bateman appears to include in his resources, but the distance of which from Stanmore is so great, that even one 4-feet pipe from Stanmore to Blackheath would be about 20 miles in length, and would cost about 230,000*l.* It is doubtful whether this rapidly increasing district could be supplied from a point 20 miles distant, without a second 4-feet main, unless the water were distributed through the Kent district with the assistance of the present establishment of the pumping engines. I need not enlarge upon this except to state that I think that the locality of London renders it extremely difficult to get a proper and ample supply of water by gravitation distributed over the whole area. It is the very reverse in that respect of Glasgow, where you have hills of great height approaching close to the city. If, for instance, you wish to supply water from Stanmore to the Kent district you must carry it 20 miles in a pipe alone. That difficulty arises from the locality of London itself, and seeing that the New River Company bring water by gravitation to about a height of 90 feet above high water, and that practically they pump the whole district, it is the best example that I can give you of the difficulty of supplying London by gravitation from one point. The distance is so great from the divergence of the districts that there must be an enormous amount spent in iron pipes to bring home the head to every part if you wish to give gravitating pressure. The present system of distributing pressure through London is from a multiple of centres by engine power, and to imitate that by gravitation from one centre would throw you practically into an enormous expense. If you wish to bring soft water to London by any such scheme I think it would be far more economical to graft it on the present system of pumping as much as you can. I do not say what the exact pressure would be, but that engine power would have to be used. For instance, you would supply the New River district with soft water from Stanmore far more economically by sending it to the New River head, and letting it be dealt with by the engines as at present than you would by attempting to put such an amount of large pipes as should bring the pressure over the district by gravitation alone. That is the conclusion to which I have come.

3441. (*Mr. Harrison.*) It is simply a question of the economy of one system over the other?—Yes, owing to the immense size and number of pipes which would be necessary to bring the pressure home from distant a point as Stanmore.

3441*a.* Still it is purely a question of cost?—Not quite purely so, because of course the Kent district would be almost impracticable without pumping. There would be no way of supplying the Kent districts except by using the present pumps; you have not pressure sufficient, as so much of the district is actually above anything that you could reach.

3442. (*Col. Harness.*) Having an elevation of 90 feet at the New River head you probably do supply a considerable portion of your district by gravitation, do you not?—No, very little; practically it is all done by the engine. It is pumped direct. There is a service reservoir on the top of Claremont Square into which they pump.

3443. Even for the low districts?—Yes. It happened in this way. In the year 1853, when filtration was put upon the company, they were obliged to lose from 13 to 15 feet out of the 90 feet then available, and the increased pressure required for the district and the larger volume of water that they had to give, I think I am right in saying, practically drove them to pump nearly all their district.

3444. Before that you did deliver a large portion by gravitation did you not?—Yes, a large portion of water was delivered by gravitation before that alteration with the limited supply that they then gave.

3445. (*Mr. Prestwich.*) Supposing London were supplied by high pressure from Stanmore that would probably necessitate a fresh system of pipes for London altogether, would it not?—Yes, a fresh system of large pipes to bring the water home into the present pipes. If you once got the water home into the centres of the various districts with pipes large enough for the purpose you would get the pressure, but as I understand the height at Stanmore, it is not sufficient to bring what you call high pressure into London, which is a height of 200 feet. I will just give an example which will explain what I mean. The Thames is now

N. Beardmore, Esq.

16 May 1867.

taken we will say by the Grand Junction Company at Hampton, and they pump it six or seven miles to their works at Kew Bridge, and to deliver it at Kew with a pressure of 90 feet; at this place they filter and begin their supplies; they have to pump with a pressure of from 190 to 210 feet, although they are within five miles of their district; again at Campden Hill the company re-pump for the upper levels of their district. The Chelsea Company only pump to their reservoirs on Putney Heath, a distance of six miles from Thames Ditton; their reservoirs are only 160 feet above their district in London five miles distant, and yet they have to pump up to 230 feet pressure at Kingston to get it up the six miles. That shows you the pressure which is required from any point at a great distance, and the size of the pipes for reducing of pressure necessary for bringing the pressure home. In fact, it is not a constant pressure or a constant supply system unless very large pipes are brought over that 10 miles to bring the supply even to the confines of London.

The witness withdrew.

H. H. Fulton, Esq.

HAMILTON HENRY FULTON, Esq., examined.

3446. (*Sir J. Thwaites.*) You are a member of the Institute of Civil Engineers?—Yes.

3447. Has your attention been directed to the question of supplying London with water?—It has.

3448. I believe you have some prepared scheme for accomplishing that object?—Yes, The plan which I propose is to take the water from the upper sources of the river Wye in Mid Wales, at a point about a mile and a half below Rhayader at the confluence of the Wye and its tributary the Elan.

3449. Have you any plan to show the gathering ground and the course of your tunnel?—Yes. This is a plan (*producing the same. See Appendices A A* (1) *and A A* (2), showing the different watersheds from which I propose to take the supply. No. 1 watershed contains an area of 93,752 acres.

3450. Can you go on to describe the other part of your district, area No. 2?—I had better state perhaps that the reason why I selected this district, is that it is very thinly inhabited, the water at present is scarcely used at all either for manufacturing, domestic, or navigation purposes, the fisheries which exist can be protected from injury; there are no manufacturing towns in the watershed, and the only application of water for mechanical purposes is for flour mills, of which there are very few.

3451. Are there any mines?—There are a few mines, but very few indeed.

3452. Are there lead mines?—Yes, but I believe within the last few months those lead mines have been given up on account of their being unproductive.

3453. Are we to understand that the several areas numbered 1, 2, 3 and 4 are all essential for the present scheme, or are they alternative areas?—No. 1 watershed, which comprises 93,000 acres, is sufficient to yield a supply of 130,000,000 gallons a day, that is after allowing the usual amount for compensation to mills, &c.

3454. Will you state to the Commission what is the rainfall on No. 1?—The rainfall which I have assumed is 60 inches per annum, the net rainfall after deducting for evaporation and absorption is 30 inches.

3455. What do you allow for absorption?—In that case the evaporation and absorption would be 30 inches.

3456. Can you separate the absorption from the evaporation?—The absorption I take at 12 inches, I have taken the two together at 30 inches.

3457. Therefore you would have a net result of 30 inches of rainfall?—Yes.

3458. And that calculated on an area of 93,752 acres would give you 130,000,000 gallons per diem would it?—Yes, after deducting for compensation that is the net quantity.

3459. I mean that then you would have at your disposal 130,000,000 gallons of water per diem?—Yes.

3460. And you would provide for compensation a portion of that, and the rest would be due to your reservoir?—Yes; the total quantity which I assume I should get would be 175,000,000 gallons from this area alone. Then I deduct from that amount 44,000,000 gallons for compensation, which leaves a net quantity of 130,000,000 gallons.

3461. Then your previous answer was not correct that the quantity of rain would be equal to 60 inches, and that, calculating that over an area of 93,752 acres, would yield 130,000,000 gallons?—The 130,000,000 would be after deducting for compensation.

3462. Do you mean compensation to the rivers?—Yes.

3463. You would equalise the flow, I suppose?—The flow would be equalised during the dry time.

3464. I presume that under that system of compensation the rivers would probably never be so low as they are now in the dry season?—Never; the flow would be more equable.

3465. But you would not have floods as now?—Not to the same extent, unless the reservoirs were full. Of course, if the reservoirs were full, the water would flow off as usual.

3466. If the rainfall mastered your storing capacity, then it would flow off into the river as it does now?—Quite so.

3467. How have you arrived at the conclusion that 60 inches of rain falls in that district?—There are no observations by rain gauges that I am aware of, except a few. I merely reason from the similarity of the district to the Lake District. I consider that as the Lake District is found to yield about 77 inches it is a safe assumption to take 60 inches for this particular district.

3468. Then you have no means except the analogy to which you have referred to determine the question?—No.

3469. (*Mr. Prestwich.*) Where is the nearest rain gauge to your proposed district?—There is one near Rhayader, which on the average has yielded, I think, 44 inches per annum.

3470. What distance is that from your gathering ground?—That is within two or three miles of the point to which I have referred as being about a mile and a half below Rhayader, but then the elevation there is very small, comparatively speaking, and the consequence is that the rainfall must be very much less there than it would be in the watershed to which I have referred.

3471. (*Mr. Harrison.*) Is the level of the river there about 625 feet above the level of the sea?—It is; the level of the reservoir is 590 feet above the level of the sea.

3472. (*Sir J. Thwaites.*) The railway which you see on the map seems to run parallel with the river?—Yes, and it crosses the river.

3473. (*Mr. Harrison.*) Is this a railway that you have made, or is it one of Mr. Robertson's lines?—It is the Mid Wales line; Mr. Piercey's line.

3474. (*Sir J. Thwaites.*) How will that railway be affected by your storing ground?—In no way.

3475. There is an embankment of 75 feet marked upon the map, what embankment is that?—That applies to the reservoir coloured red.

3476. Is it in a valley?—Yes, the land is steep on both sides.

3477. Do you propose to dam the valley?—Yes, I propose to make the reservoir by placing a dam across the valley 75 feet high.

3478. What width would your dam be at the top?—About 12 feet.

3479. I suppose it would be constructed in the ordinary way with a centre of clay puddle ?—Yes.

3480. What do you construct the other part with ?—The slopes would be faced with stone where it was exposed to the wash of the water, but on the other side of the embankment it would be simply a slope.

3481. I suppose you would have a slope on both sides ?—Yes.

3482. To what extent ?—On one side it would slope about two to one, and on the other side I should say about four to one.

3483. Do you think that would be sufficient to resist a pressure of 75 feet ?—Yes.

3484. (*Mr. Harrison.*) You say that at the rain gauge at Rhayader the actual rainfall by the returns is something about 44 inches ?—Yes.

3485. That being so, on what basis do you calculate that there would be 60 inches in area No. 1 ?—Because you will observe the watershed is very greatly elevated. This is the ridge of the hill, and you will find a number of levels marked which show the heights above the sea, and there is the mountain of Plynlimmon which is of the height of 2,467 feet.

3486. (*Sir J. Thwaites.*) You have to make up the deficiency of 20 inches, so that you must have a very large rainfall indeed upon some of those higher parts ?—Yes, so it would be. My opinion is that the rainfall, taking the minimum on those ridges, would be 60 inches, and therefore if I deduct 30 inches for evaporation and absorption, I consider that that is a very safe amount to calculate upon.

3487. If I understand you rightly your calculation is based upon a given rainfall of 60 inches over the whole of that area, but if in part of No. 1 area the rainfall is 44 inches only, you must have a very large rainfall in the other parts of the district ?—But I allow a large margin I consider in the 30 inches.

3488. (*Mr. Harrison.*) Is there not a rain-gauge at Llanidloes ?—Yes, but that is not at any higher level than the one at Rhayader.

3489. What was the rainfall of that gauge ?—It was about the same as at Rhayader.

3490. Then with regard to the rainfall the only guide over the whole of this district that you have embraced in your scheme is practically the Rhayader gauge ?—That is the only point that I am aware of at which a rain gauge has been kept.

3491. (*Sir J. Thwaites.*) Your deduction is that if there is 76 inches of fall in the Lake district, you are safe in taking 60 inches as the fall in this area, which you have described as No. 1 ?—Yes.

3492. (*Mr. Prestwich.*) That would be for a mean of how many years ?—That would be the minimum of the driest year. I am not speaking of the minimum of the Lake district, but of the minimum of this Welsh district.

3493. But you take the Lake district as one point of comparison, and you say that the Lake district is a very rainy district, and that this will follow in a somewhat similar ratio, but in the Lake district there are years when the fall is below 60 inches ?—Yes, that may be so.

3494. Therefore you would hardly place that district on a level with the Lake district ?—I do not see why it should not be so. There are the same causes operating here that are operating in the Lake district. I do not see that there should be any difference. The absorption must be very much the same, because the character of the soil is the same, and the evaporation must be the same.

3495. (*Sir J. Thwaites.*) The question now is the amount of rainfall, because that is the foundation of all your calculations; you really have no data as to the amount of water that would be produced in that area ?—There are no rain gauge observations.

3496. You assume, of course, that if the gauges had been placed at other parts of the district you would have had very much larger results than you have at Rhaiader ?—Yes.

3497. (*Mr. Prestwich.*) Would you not consider it to assimilate more to the rainfall in Mr. Bateman's district ?—I should think it must be precisely the same, because it is so very near it. I have another map (*producing the same*) which will show the relative position of my district and Mr. Bateman's. The Severn scheme district is coloured brown.

3498. (*Sir J. Thwaites.*) In fact you are only separated by a ridge ?—Yes, only by a ridge. I may say that if I were to take the same amount of absorption and evaporation which is allowed for the Severn scheme, which is 12 inches, the quantity which I have stated would be arrived at by a rainfall of 42 inches instead of 60 inches.

3499. (*Mr. Harrison.*) Your calculation is that the districts Nos. 1 and 2 would yield 243,000,000 gallons a day, and Nos. 3 and 4 would yield 150,000,000 ?—Yes.

3500. And that the four districts together would be about 393,000,000 gallons ?—Yes.

3501. On the assumption that you have a net available quantity of 30 inches ?—Quite so.

3502. Have you at all turned your attention to the possibility of a portion, and the largest portion of any aqueduct to London being made available for the district suggested by Mr. Bateman and by your own scheme ?—Yes.

3503. You apparently cross each other ?—Yes.

3504. Where ?—The point appears to be near Bromsgrove. I do not know that I have Mr. Bateman's plan correctly laid down on this map, but it is near Bromsgrove. If the levels of the aqueducts could be made to accord at Bromsgrove, they could run together from that point to London.

3505. Even taking that view of it, assuming that your calculations of the rainfall were erroneous, and that they were not half of what you calculated, the two systems together would be able to supply beyond any question all that could be wanted ?—I should think there could be no doubt that they would supply far more than could be wanted.

3506. And that involves, of course, the question of cost ?—Quite so.

3507. (*Mr. Prestwich.*) Have you gauged any of the streams so as to check the rainfall ?—I have not done so for this reason, that in a river like the Wye the fall is so rapid that it would be a most difficult thing to tell when the proper time would arrive for taking the gauging, and I do not think that the result would be any criterion as to the quantity of water which the watershed would yield.

3508. (*Sir J. Thwaites.*) Starting from your gathering ground, how many reservoirs do you propose to form on the ground ?—I have only dealt at present with No. 1 area as far as regards the provision of reservoirs. The number which I propose there are six.

3509. What would be your storing power in those six reservoirs ?—The quantity which those reservoirs would be capable of storing would amount to 26,000,000,000 gallons, which would be equal as I consider to 150 days' supply.

3510. What do you calculate the necessary supply for the metropolis to be ?—I have assumed 130,000,000 gallons a day, but the present consumption of London I believe is about 90,000,000.

3511. How many gallons per head per diem ?—About 30 gallons.

3512. That includes the supply for all purposes, does it not ?—Yes, for all purposes. I think that is about the average of what London at present requires.

3513. Then No. 1 area would be equal to the present requirements of the metropolis ?—It would be equal to 130,000,000 gallons, which according to the present supply would be about 40,000,000 gallons in excess.

3514. Now will you please to follow on the description of your scheme ?—The reason why I have chosen the Wye district in preference to any other is, that the importance of the navigation of the Wye is very small, and consequently the abstraction of its water would be no injury as far as the navigation is concerned. Indeed from the sea up to Hereford, which

H. H. Fulton, Esq.

16 May 1867.

is the largest town in the district, and which has a population of between 15,000 and 16,000 inhabitants only, I believe the trade is nearly extinguished on the river, that is to say, it is nearly superseded by the railway, and the only trade by navigation which exists now is by the canal from the Severn, which runs up to Hereford.

3515. Would the equalization of the floods cause the mouth of the river to silt up at all in point of scour?—I think that the abstraction of that large quantity of water from that watershed might certainly affect the navigation.

3516. And the effect of the scour of the floods would be neutralized by your principle of compensation?—I do not think it would. I think that a certain amount of injury would arise to the navigation by the abstraction of this large quantity of water from the watershed.

3517. You state, do you not, that there are several flour mills on that stream?—Very few, I believe.

3518. Is the water power there utilized at all for other purposes than grinding corn?—No, I am not aware of any. Below the point where I take the water there are no mills, I believe, whatever.

3519. Now will you describe the course which you propose to take from your reservoir?—The point from which I propose to take the water, as I before stated, is about a mile and a half below Rhayader. At that point the conduit would commence, and go along the eastern side of the valley of the Wye to a point on the river Ithon, where another reservoir could be constructed of considerable capacity. From that point the conduit would be continued to the north-east of Builth.

3520. (*Mr. Prestwich.*) What height above the sea would the reservoirs be?—The upper reservoir would be 590 feet, the lower one would be about 512 feet on the river Ithon, and from that point the conduit would continue along the valley of the Wye, past Glasbury and Hay to the north of those towns, and from thence somewhat to the south of Kington, to the south of Ludlow, to the north of Tenbury, to the south of Bewdley, to the north of Stourport, to the north of Bromsgrove, near to Henley-in-Arden, Warwick, and Banbury, to the north east of Bicester, to the north of Aylesbury, Tring, Berkhampstead, and Watford, to a point near to Totteridge near Barnet, where I propose to construct a service reservoir.

3521. (*Sir J. Thwaites.*) At what height above high water?—It would be at the level of 276 feet above Ordnance datum.

3522. (*Mr. Harrison.*) How far from the Marble Arch?—In a direct line from the Marble Arch it would be eight miles.

3523. (*Sir J. Thwaites.*) What would be the size of your tunnel or aqueduct?—It would be 15 feet wide and 14 feet 6 inches high.

3524. What fall do you give?—The fall would vary from six inches per mile to two feet per mile.

3525. What is the discharging capacity?—It would be equal to a delivery of 230,000,000 gallons a day. Of course the delivery depends entirely upon the velocity, and that I think can be regulated.

3526. Do you give a uniform fall, or do you propose to check it by weirs?—Wherever it was found necessary to do so it would be checked by penstocks and over falls. This section (*producing a section*) shows the section of the country through which the line passes; it is of course only an approximate section. I do not pretend to say that it is correct in detail.

3527. I presume that you must have iron pipes?—Yes, where the valleys are deep.

3528. Do you propose to go through the valleys by means of syphons?—No, in ordinary cases the valleys would be crossed by embankments. The Severn is crossed near Bewdley, and there of course the water would be taken across by a syphon.

3529. (*Mr. Harrison.*) How has that section been prepared?—The section, so far as the end nearest the watershed is concerned to which I have referred, is taken from actual levels.

3530. How far from actual levels?—I should say seven or eight miles, and the rest is made from the Ordnance levels and from the sections of railways and canals, from which I have been able to compile this section. There is a total available fall from the watershed No. 1. to London of 314 feet. Of course the arrangement of the inclines would depend as I said before upon how the permanent section may turn out.

3531. (*Sir J. Thwaites.*) Have you made any estimate of the cost of the scheme as a whole?—I have made an approximate estimate of the cost of the first 130,000,000 gallons which amounts to 7,000,000*l.*

3532. What does that include?—It includes all the works from the reservoirs to the service reservoir, and the connexion with the existing system of pipes in London, including the reservoir at Totteridge.

3533. Of course you have made this section as you state from levels of canals or railways as you could best collect information?—Yes, and from the Ordnance surveys.

3534. Your estimate therefore must be an approximate estimate?—Of course. To make a permanent survey of the whole matter would require a very large expenditure, and occupy a considerable amount of time.

3535. Have you made this estimate, such as it is, from the materials at your disposal a full estimate?—I think it is ample.

3536. I understand that the 7,000,000*l.* sterling includes all the cost of the gathering ground, the formation of the reservoirs, your aqueduct, tunnels, the service reservoir at Totteridge, and the connexion with the London system of distribution?—I do not of course propose to pay any compensation for the gathering ground, because that gathering ground would not be interfered with in any shape or way.

3537. You simply purchase that which you will occupy by the reservoirs?—That is all.

3538. You do purchase that?—Yes, certainly.

3539. Have you made any calculation as to the compensation to the millowners and other parties on the stream of water of which you intercept?—The millowners would be compensated by water and not by money.

3540. Have you not estimated any money compensation to any party on the Wye?—Only in cases where they would be interfered with by the reservoirs. If the sites of their mills were interfered with by the reservoirs, of course they would require compensation.

3541. With regard to those lead mines within your gathering area, do you propose to purchase the interest in them, or how are you to deal with their washings?—Anything that was likely to pollute the water I should propose to divert from the reservoirs.

3542. And have you estimated the probable cost of that?—Yes, and I have included that in the 7,000,000*l.*

3543. How many miles long is your tunnel?—180 miles is the whole length of the conduit.

3544. (*Mr. Prestwich.*) How many miles would be tunnel?—The covered portion of it would be 60 miles, and the tunnelling portion would be 18½ miles.

3545. (*Sir J. Thwaites.*) Does your estimate include compensation for easement in places where you occupy the surface?—Yes, of course, in cases of this sort I have put down a lump sum which I consider sufficient to cover everything.

3546. Have you had regard to the question of compensation for easement and for actual purchase and for severance?—Yes, all that is assumed to be included in my estimate.

3547. (*Col. Harness.*) What guided you as to covering the portions of the channel that are not in tunnel?—The nature of the soil to a great extent.

3548. You make a culvert of it altogether do you not?—For portion of the line I do.

3549. Have you covered any portion of it that is not a culvert?—Yes, the distinction between the covered portion and the tunnel is simply that the one

H. H. Fulton, Esq.

16 May 1867.

is cut open and covered again, and the tunnel of course would be in tunnel, it would not be an open cutting; as regards the shape of the culvert that would be the same in both cases.

3550. Why have you covered it in the portions that are to be made open cutting?—Because it is desirable to do so where it approaches thickly populated districts, where the water would be liable to be polluted.

3551. (*Sir J. Thwaites.*) How do you intercept from your channel the surface water and the drainage from land under cultivation, polluted by manures; have you any arrangement for that purpose?—There would be no water draining into the conduit in any case from cultivated lands.

3552. I suppose, as a principle, you exclude all drainage from the water?—Yes, all drainage would pass through the present channels. Wherever a drain was crossed, of course the drainage must be provided for by a culvert, and not be in any way interfered with.

3553. What time do you think it would occupy to complete this scheme after parliamentary powers were obtained?—I do not see any reason why it should not be completed in the course of five or six years. I do not think that the heaviest portion of the work would require a longer period than that.

3554. (*Mr. Harrison.*) Of course the heaviest embankment of your reservoirs would be the measure of the time?—Yes. If they were properly made the consolidation would be very small indeed.

3555. (*Mr. Prestwich.*) With regard to the work itself, you have stated that there is to be 18½ miles of tunnelling and 91 miles of cutting; what is the remainder?—The lengths that I gave were these: the length of the open portions was 91 miles 13 chains, the covered portion was 60 miles, the tunnel was 18½ miles, and the inverted syphons 10 miles 27 chains, making a total of 180 miles. Of course that is only an approximate calculation, as I said before, and the measurements could only be properly arrived at by a more thorough survey.

3556. (*Mr. Harrison.*) Do you propose to put your estimate in?—Yes, I will supply it to the Commission.

3557. I think I understood you to say that the sites of all your reservoirs have been actually levelled?—Yes, they have.

3558. Have you ascertained what the nature of the strata would be upon which your embankments would be made?—Principally rock and clay. I think that in every instance there is clay as regards those reservoirs which I have shown the Commission upon the plan.

3559. Have you had sections also taken of the areas of those reservoirs, from which to calculate their capacity?—Yes, I have.

3560. Have you also a section of the open conduit?—Yes (*producing the same*). The open portion would be 36 feet wide at the top and 18 feet at the bottom, with slopes of 1½ to 1, the depth being 6 feet. Of course that cross section would be modified according to the fall that would be found necessary.

3561. Do you propose to line it throughout from end to end?—Yes, I propose to line it either with puddle or with concrete. Of course, where concrete was used it would be a different section altogether, and if it were through clay the puddling would be unnecessary.

3562. Would you trust to an aqueduct of this nature without any lining at all except merely the puddling?—Where it was solid clay, I should think that lining would be unnecessary. Of course I mean that instances of this kind would occur.

3563. You assume, do you not, a fall of one foot per mile?—Yes.

3564. Then in that you would have penstocks, of course, to regulate the flow?—Yes.

3565. (*Col. Harness.*) What velocity do you allow in this open cut?—A velocity of 157 feet per minute.

3566. That is unchecked by penstocks?—Yes, that is with a fall of one foot per mile. It would depend very much upon the curves which might exist upon the line of the cut.

3567. (*Mr. Harrison.*) You would hardly, perhaps, give a fall of a foot per mile through that open conduit through clay without its being lined?—Not unless it was checked by penstocks, I think.

3568. No doubt you have abundance of fall, and you could give a greater fall where you cross the valleys, if it is desirable?—Quite so.

3569. The only question would be the estimate, if it were found necessary to line your conduit throughout?—Wherever the fall exceeded a certain inclination, I should think it desirable to line the cut.

3570. But your estimate of 7,000,000*l.* is not made upon the assumption of lining your conduit?—It assumes it to be lined throughout where the inclination exceeds a certain limit.

3571. What is that limit?—I should say about 4 inches per mile.

The witness withdrew.

Adjourned to Thursday next at 11 o'clock.

Thursday, 23rd May 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq
JOSEPH PRESTWICH, Esq.

Capt. EDWARD BURSTAL, R.N., examined.

Capt. E. Burstal, R.N.

23 May 1867.

3572. (*Chairman.*) Are you the Secretary of the Thames Conservancy Board?—I am.

3573. You have been for a great number of years connected with the River Thames, have you not?—A great many years.

3574. How many years?—I have been nearly 10 years Secretary to the Conservancy Board, and for many years before that I was connected with the Thames, and having made surveys of the river for the Government on and off many times since 1833.

3575. You are therefore well acquainted with the River Thames and all its tributaries?—Yes.

3576. And with the whole of the district through which it passes?—Yes.

3577. Will you tell us briefly what are the duties of the Thames Conservancy Board, especially with reference to the new Act?—The Thames Conservancy Board under the powers conferred upon them by the Act of last year are empowered to keep the river in order both for the purposes of navigation and for the purposes of keeping the water in a pure state for the metropolis for drinking purposes.

3578. (*Col. Harness.*) Between what points?—Between Cricklade westward and Staines eastward by the last Act, and by the former Acts from Staines westward to Yantlett near Southend eastward.

3579. (*Chairman.*) In fact you go from Cricklade to Southend?—Yes, to Yantlett near Southend.

Capt. E. Burstal, R.N.

23 May 1867.

3580. (*Sir B. Phillips.*) Is that the extent of your jurisdiction?—Yes.

3581. (*Col. Harness.*) Does your jurisdiction include the tributaries of the Thames?—The jurisdiction of the Conservators does not extend up the tributaries for navigation purposes, but only for the purpose of keeping the water pure, and that jurisdiction extends three miles in a straight line from any part of the river where those tributaries may flow into it.

3582. (*Chairman.*) Will you tell us what powers you have for keeping the Thames water pure, and how you practically exercise them?—There are clauses in the Act of Parliament which empower the Conservators to prosecute any persons who may throw or allow to flow into the river any impurities whatever; and the Conservators have ever since they have been in office encouraged informers to come to them and give them every information as to persons who allow filth to flow into the river, or throw it into the river; and they have taken proceedings innumerable almost against persons who have committed this breach of the law, and they pay rewards (generally speaking they are rewards of 40*s.*) to informers who get convictions for those offences. With regard to the upper part of the river which has lately come within the jurisdiction of the Conservators, what the Board have done has been to give orders to all the lock-keepers to collect all refuse and deleterious matters which shall accumulate at the weirs. They have supplied them with rakes and so on, and whenever any dead animals or refuse of a foul character collects at those points those lock-keepers get them out, and dig a hole in the towing-path and bury them. In addition to that the Board have ordered a little craft, a sort of screw tug, to be built, and she is just completed at Bristol; and on board that vessel will be men whose duty will be to inspect the river, and whenever on their passage from Oxford downwards, or in any part of the district where they go, they meet dead animals or any other refuse of an improper character, to rake it out of the river and bury it at once. This has been done to a very considerable extent already, but it will be done we hope in a perfect manner when this little vessel comes into work, which will be in the course of a fortnight or three weeks.

3583. What do you do as regards sewage and matters of that kind?—What the Board have done with regard to sewage has been this, they have complied with the requirements of the Act in giving notices to all the towns on the river to discontinue the discharge of their sewage into the Thames.

3584. Does the Act apply to particular towns, or to towns of a particular size?—It applies to every town, or every person in fact who ejects sewage into the river as far as that goes, but what the Board have done has been to issue notices to the town councils, and boards of health, and sewage authorities of the various towns, such as Oxford, Abingdon, Marlow, Reading, Windsor, and other places which I do not remember at the moment. Those notices have been served requiring them to discontinue discharging the sewage of those towns into the river within a period of 13 months.

3585. Has that time expired?—No, the notices have only been issued about three weeks or a month.

3586. What will be the course that will be taken by those towns?—It is very difficult to answer that question, because of course it remains with them to decide as to how they will dispose of their sewage. Whether it will be by settling tanks, and then the water percolating through a material which will render it innocuous, it is difficult for me to say, but it is a question more for the engineer to decide than it will be for me.

3587. Putting it in the other way, in the event of their not complying with your orders, what course do you take then; supposing you find that the sewage at Windsor for instance is allowed still to go into the river instead of being kept out of the river, what would be the course taken by the Board?—The Act of Parliament provides that they shall be fined 100*l.* at once, and 50*l.* a day for every day they neglect to do it after the time of notice has expired.

3588. Is that fine to be inflicted upon application to the magistrate, or who puts the law into force?—I rather think it is; I am not quite sure whether it is the petty sessions or not.

3589. Do you believe from your knowledge of the river, and the towns upon the river that the powers of that Act are sufficient, and that you will be enabled to keep the river pure from those pollutions by means of that Act?—I think to a very great extent we shall.

3590. Assuming that the water which now flows into the Thames from those various places is of necessity impure from the drainage of the towns which are upon the river, and the various impurities which come into the river at different parts, do you think that by means of this Act you will be enabled to say that the water of the Thames shall in future be pure?—I think whatever steps are taken with the view of altering the system of drainage, instead of allowing the drainage to go into the river as it does at present thick and thin, by adopting a means of draining it into large tanks and allowing it to percolate into the river in a limpid form instead of being in a turbid state as it is now, the waters will be deprived of a very large quantity of the organic matter which exists in it at present, and therefore, of course, the sewage in that form will be very much less pernicious than the sewage which flows in at present.

3591. (*Col. Harness.*) But there will still be a flow of the residue of the sewage into the water?—Not provided they adopt that system; I cannot tell that they will adopt it. If, however, such a system should be adopted there would be a flow of material into the river which would be charged with a certain proportion, but at present the Board are not authorized to recognize any such thing.

3592. Have you any power to stop such a flow?—Excepting by the notices which I have referred to; those would stop it, I presume.

3593. (*Chairman.*) You will have the power under the Act of bringing offenders before a magistrate and complaining that they allowed any portion of their sewage to come into the river?—Yes, and upon that being proved would be fined.

3594. (*Col. Harness.*) If the sewage were collected in tanks not far from the river, and the material between were such that it could percolate through, could you prevent that?—I really think so, if that material was found to be deleterious.

3595. What is the title of the Act to which you refer?—It is the Thames Navigation Act of 1866.

3596. (*Sir. B. Phillips.*) What is the constitution of the Board of the Thames Conservancy?—The constitution of the Board is the Lord Mayor of London, two of the Aldermen, four of the Common Council, two members sent by the Admiralty, two members sent by the Board of Trade, and two from the Trinity House, and there are two representatives of ship owners, two of lightermen and barge owners, one representative of dock owners and wharfingers, one representative of owners of passenger steamers, and four members elected under the Act of last year for the upper district, making 23 in number, I think.

3597. Has that Act been put in force with regard to the election of the four last members you have mentioned?—Yes, those members have been elected.

3598. What are they?—They are land owners; one of them is a miller, and has mill property on the river. Mr. Clutterbuck, the clergyman, who has been examined before this Commission, is one, Mr. Harcourt is another, and Mr. Hedges another.

3599. Do you know what quantity of water the existing companies are allowed to draw from the Thames for their daily supplies?—According to the arrangement made with the corporation of London in 1852 the limit is 20,000,000 gallons a day each of them.

3600. How many companies are there?—Five companies.

3601. Have you ever considered what additional quantity could be drawn from the Thames?—An enormous quantity more than is drawn already without the river feeling it above Teddington Lock to any great extent.

3602. (*Chairman.*) You say that they have the power to draw 100,000,000 gallons per diem from the river, can you tell me what quantity they absolutely draw now?—Yes, I can, because we have a monthly report from each of the water companies sent to me of the average quantity during the month per diem, and it comes out in this way, that on the average for the last four months the Chelsea Waterworks Company have taken 7,500,000 gallons a day, the Grand Junction 8,700,000 gallons, the Lambeth 8,500,000 gallons, the West Middlesex 8,400,000 gallons. The Southwark and Vauxhall have made no return, but assuming the Southwark and Vauxhall to be 8,500,000, which is rather more than the average of the others, that will make the average per day for each of the companies 8,300,000 gallons.

3603. Do you consider those five months a fair test? are they the water consuming months?—No; those have been the winter months. I think in fairness we should put perhaps 25 per cent. on to that quantity for a fair average for six months.

3604. If you were to call the six summer months 9,000,000 per company, do you think that that would be within the mark?—Yes, I should think it would be so, taking it for nine months of the year.

3605. (*Col. Harness.*) Then they really do not draw more than half their supply?—They do not draw one half. I think the water companies consider that in round numbers they draw about 8,000,000 gallons a day each of them through the year. I think it would be a little more than that as those figures would show.

3606. (*Chairman.*) And they are entitled to take 20,000,000 gallons each?—Yes, they are entitled to take 20,000,000 gallons each by the agreement made with the corporation in 1852.

3607. Can you state whether the quantity that they take diminishes in any appreciable degree the quantity of water in the Thames?—We do not observe it at all. We have never found the water fall short of flowing over Teddington lock.

3608. Is Teddington lock a sort of test?—Teddington lock is the last lock, where the water passes over the tumbling bay at Teddington lock, and there has never been any diminution to any appreciable amount in the flow of water over Teddington lock. That is what is stated by the lock-keeper, who has been there for many years.

3609. Would that apply to the driest season that we have had the last 20 years?—I do not exactly know that, because I think that the failing of the water below Teddington lock has been attributable to a great extent to abstracting the water from the river above, and thus get less water to run down from Teddington to Richmond; and I do not think from the observations which were made in 1821, compared with the observations which have been made within the last few years, that there is more than two or three inches vertical difference in the average height of the water at summer levels at Richmond now compared with what it was then.

3610. (*Sir B. Phillips.*) You say that they only draw at present about one half what they are permitted to draw; supposing they took the whole of 100,000,000 gallons per diem, what effect would that have upon the river?—I have no doubt that the water would sink below Teddington lock, or taking Richmond as a point the water would subside to some extent, but not very much.

3611. Not in any way to impede the navigation?—No, the navigation is not affected there by the land water so much as it is by the tide water. All the navigation of the river from Teddington lock down to Putney is a navigation contingent entirely upon the tide and not upon the land water at all, or scarcely so.

3612. Supposing it were necessary to draw a very much larger quantity from the Thames for the supply of London, could the supply above that district be in any way increased by the tributaries at present in existence?—What I have thought is this, that supposing it to be in practice considered necessary to husband the water of the Thames I think it might be done in a very effective way by making reservoirs in the upper district probably, before you come to the populous towns, such as Oxford; say seven miles above Oxford.

3613. (*Chairman.*) Have you turned your attention to the possibility of making one or more reservoirs, and if so, in what district do you propose to make them?—I have heard this subject discussed by some engineers, by our own engineer, and by Mr. Beardmore also, and it appears to me that reservoirs could be made about 7 miles above Oxford near Ensham of a very large and capacious character, to store during the wet weather an enormous quantity of water which would never be missed in weather of that sort in Oxford; in fact they would be rather glad to get rid of it, as it would prevent some of their low-lying districts from being flooded, and that storage could be made so as to supply any deficiency that might occur in the lower part of the river. What I mean by the lower part of the river is the part near Hampton where the present pumping stations of the water companies are.

3614. And that would be a supply to meet the emergency of a very dry year?—I should think it would be only required in a very great emergency, in very dry weather; but in the ordinary state of the river, in its normal state the river is capable of supplying a very much larger quantity than is already taken from it. The reason why I have come to such a conclusion is that when the Colne Water Bill was before the House, some years ago (I think it was as far back as 1860, although I am not quite sure of the year) the Conservators were desirous of getting the opinion of the celebrated engineer, the late Mr. James Walker, they were not quite sure in their own minds whether if an abstraction of 10,000,000 gallons per diem was made at that part of the river which is near Staines, where the Colne flows into the river Thames, it would not be inimical to the navigation, and Mr. Walker told us that if the evidence that he could give would be of any assistance he would readily give it, but that it would certainly be to this effect that it would not be more than the thickness of a sheet of paper over the surface of the river below the point of abstraction.

3615. Then you probably did not call him as a witness?—No; the Board considered that with such an opinion as that from such an eminent engineer, the thing was not of sufficient importance for them to oppose the Bill.

3616. Are you able to give the Commission any opinion as to the quality of the water which is supplied to London?—I have not turned my attention much to that subject. I have read the tables of comparison between the water that is supplied from the Thames and that from other sources.

3617. Have the Board to which you are secretary had any complaints made to them of the quality of the water supplied to London?—No, we have never had any complaints of that kind at all.

3618. Probably they would not be the proper body to go to?—I should think after the Act of 1866 the province of the Board being to keep impurities from the water, most likely if there were a ground of complaint that complaint would be sent to the Board, but at present we have had no complaint whatever.

3619. But that Act would hardly have been a sufficient time in operation, in fact your powers have not been exercised?—I think not. We have scarcely got into harness, one may say.

3620. (*Mr. Harrison.*) According to your observations, is the head of the river now lower than it used to be in your recollection, taking it at Hampton?—No, I think not at Hampton, that is above Teddington lock.

Capt. E. Burstal, R.N.

23 May 1867.

3621. Is it at Wandsworth?—Yes, it is at Wandsworth. I was employed by the First Commissioner of Works in 1856 and 1857 to make a survey of the river, and I made a very minute survey and I reduced all the bed of the river in the same manner as an engineer would reduce any other valley, and I compared the levels with the levels taken in 1821 and I found there that the water had subsided, that the low-water surface of the river was lower in 1856 and 1857 than it was in 1821.

3622. To what extent?—I think it was nearly two feet lower at Putney than it was formerly, but that is only at one particular point. If you take it up to Richmond and so on you would find it less, and at Teddington less again, and so on, it just depends upon what part of the river it is, but I made out some tables which I lent Mr. Harrison, which would tell exactly what the difference was.

3623. (*Col. Harness.*) That would be before the removal of the old London Bridge, would it not?—The observation made in 1821 was of course before the removal of old London Bridge. My observations made in 1856 were after, and in my report to Parliament which I delivered to Sir Benjamin Hall, who was then the First Commissioner of Works, the report of February 1857, you will observe my remarks on the exact state of the river at that time as compared with the state of the river before, and also my reasons why I thought such should be the case.

3624. Have you any records of the changes which have taken place since?—We have records in our office, but they have not been of such a magnitude or anything like such a magnitude in proportion in the last 10 years as they were for those 20 or 30 years before.

3625. (*Mr. Harrison.*) Is it a fact that within the last 10 or 15 years, the low-water surface of the river has lowered?—Yes, it is so.

3626. That is principally owing, is it not, to the improvements which have been making in the river down below, and the dredging works which you have been carrying on lower down?—No doubt. But I should like the Commission perfectly to understand that the improvements which have been made below London Bridge can have had no effect whatever upon that. If you study the tidal wave of the river with diagrams drawn from it, you will certainly come to the conclusion that whatever dredging you do below London Bridge can never affect the river in the western part of it. The great changes which have taken place have no doubt to my mind been consequent upon the removal of old London Bridge, and then since that there has been the removal of Westminster Bridge, and since that again there has been the removal of certain shoals which were visible every day below Westminster Bridge and Waterloo Bridge. All those banks which showed above water at low water acted as dams to not only the tidal water but to the actual river water, and the removal of those things has no doubt to my mind, caused a considerable portion of the up-river water to escape and thereby reduced the low-water surface in all points of the river to the westward.

3627. Taking that to be so, it is quite obvious, is it not, that the navigation up to Teddington must depend a great deal more now upon the tidal water than it used to do formerly?—Yes, in one way it does, but generally speaking, it does not, and I will endeavour to explain that. The navigation is still in fact all the way up to Putney, as it always has been; barges, and so on, get up to Putney at low water, if they have a fair wind, and can sail against the stream, there they have towing horses—they are nearly all towed by horses—the towing-path commences there, and they now, as they always did before, tow when the flood makes (and the navigation is during tide time), and they have got just as much time and just as good a navigation from Putney to Teddington now as they always had on the flood tide, but where the navigation has suffered to some little extent has been on the ebb tide. In consequence of the removal of the obstructions which I have just referred to on the receding of the tide the ebb runs off more quickly than it did formerly, and the consequence is that barges and craft which used to be able to hang on at Teddington and that neighbourhood for perhaps two hours or two and a half hours after high water are now obliged to be off and get away as soon as they can after high water, or else they are caught from the water draining off more quickly.

3628. We have had it in evidence that the minimum quantity of matter ever passing over Teddington lock would be something like 350,000,000 gallons a day, can you confirm that statement?—That is exactly the quantity that I have got. The lowest quantity that we know over Teddington weir is 350,000,000 gallons per day in dry summer weather—that is, of course, after the present water companies have abstracted their water.

3629. Which would make it something like 400,000,000 gallons?—Yes.

3630. Did you ever hear that on some particular day that quantity came down to 305,000,000 gallons?—No, I have not, and I have asked our engineer whether he has ever taken sufficient gaugings, and he says that Teddington weir, from not being quite so level as it might be for gauging purposes, it is rather difficult to get such good gaugings over the top of that weir as would give very correct estimates.

3631. Your Conservancy Board are going to make Teddington lock into a gauge, are they not?—I have heard that it is proposed to make the weir at Teddington of such a character as to enable proper gaugings to be taken in it.

3632. Have not the present water companies under the Act of last session to contribute each 1,000*l.* a year towards the Conservancy?—Yes, they have, making 5,000*l.* altogether.

3633. And you have an absolute power under that Act to exclude all direct drainage into the Thames of every sort and kind?—Yes.

3634. Is there any provision as to the way in which that is to be met by the towns?—No, there is not. That is left to them to manage themselves.

3635. Have you the power of seeing that when it does come into the Thames it has either been used on the land, or that it is purified?—Yes, certainly.

3636. What is to be the measure of that purification?—As I said before that purification and the manner in which it is to be purified must be left to the towns themselves and their engineers. If they settled the sewage in tanks and let it run off when it was foul, the Board would oppose it and would not allow it.

3637. Do you know whether you have any special power by your Act as to testing the extent of that purification?—No; but I should think that if any fluid ran into the river, what the Board would do would be this: they would cause it to be analysed, and if it was of an improper character after that they would insist upon its being stopped. I should think there is no doubt about our having that power.

3638. I suppose that the question of forming reservoirs in the Thames is one to which you have had your attention directed?—Yes; it has often been spoken of in case of any necessity, and the water companies, I believe, have rather anticipated that.

3639. From your knowledge of the Thames you do not anticipate any difficulty on that point?—No; I have been from Oxford all the way down the river three times within the last two months, and there is an enormous quantity of water in the river now.

3640. (*Sir J. Thwaites.*) With regard to the power of the Commissioners under the Act of last session you have already given evidence?—Yes.

3641. The local authorities will have to deal with their sewage?—Yes, I presume so.

3642. Either by deodorization or utilization?—Yes; they must deal with it or interfere with it in the best manner they can; whether it comes into the river in a pure state is for their consideration.

3643. Have you power under the recent Act to

stop the discharge of the water that may be the result of settling tanks; supposing, for example, that one of the local authorities should elect as the cheapest process the running of all their sewage into a series of tanks and allowing the water to run off, and dealing with the solid matter precipitate, have you power under that Act to prohibit the discharge of that water into the Thames?—No; I should think not if that water was rendered innocuous, and if on analysis it turned out to be completely free from organic matter.

3644. That should not be so, because you would have held in solution all the most poisonous properties?—If that were the case the Board would object to it, no doubt.

3645. Have you power under that Act to prevent that?—Yes, I should think so. I think it is quite clear that if that fluid after having escaped the settling tanks came into the river in a noxious state and charged with organic matter, the powers granted to the Board would be quite sufficient to prevent its flowing into the river.

3646. Do you know at all the views of the local authorities with regard to this question?—I think that some of the local authorities are rather glad that some steps have been taken; others are puzzled very much to know what to do with it. There is no doubt that it must be a difficult question.

3647. What is the date when they must take steps?—Not less than 12 months from the date of the notices being given, and then if difficulties arise in their mind they can apply to the board to have an extension, such extension not to exceed three years.

3648. Would the first action be a notice by the Conservancy Board to the local authorities that on and after a certain date any discharge of sewage into the Thames should be prohibited and subject the parties to penalties?—Yes, those notices have been issued, that on and after the date of the 13 months from the service of the notice they are to discontinue the notice, stating the Act and the Clause in the Act.

3649. Have you given notice to all the local authorities?—Yes, to all of them.

3650. Beyond the metropolitan area up to the extent of your jurisdiction?—Yes, all up to Oxford inclusive.

3651. Have any of the towns applied for time to make arrangements?—None whatever.

3652. Has the time of your notice expired?—No.

3653. What was the extent of the time given in the notice?—Thirteen months.

3654. You anticipate, I presume, an application for extension of time, because sewage works cannot be carried out in 13 months?—No, I should think not, it is a short time, but still it gives them sufficient time to think over the matter, and if they have got any scheme by which they can get rid of their sewage in another way I have no doubt they will apply to the Board and an extension of time will be given them.

3655. Have you power to deal with the tributaries of the Thames?—Not for navigation purposes, but we have power to deal with all the channels, whatever they may be, within three miles in a straight line from the river Thames, at right angles to the course of the river.

3656. Take the Wandle, for example, have you any power to deal with those paper manufacturers which are on the Wandle?—We gave notice only a short time ago to one paper manufacturer, Mr. McMurray, to discontinue the flow of some matter that was flowing from his mill into the river.

3657. And you have power to deal with that case, have you?—Yes, we can deal with that like any other nuisance, as we have done in hundreds of instances in the river. If Mr. McMurray puts foul stuff into the river, and we found by analysis that it was bad, he would be brought before a magistrate and punished.

3658. It was the infirmity, was it not, of your previous Act that you could not travel up those streams?—No, that power was given in the Act of 1864.

3659. That Act is now amended?—Yes.

3660. You feel that you have now power to protect the Thames from pollution, either through its tributaries or immediately from its banks?—Yes. Our inspectors go up all its tributaries within three miles and trace any foul matter, and if there is anything important they report it to the Board, and notice is given to the parties, in fact no notice is given in a case of that sort, they would be brought up before a magistrate at once as in an ordinary case of nuisance. We have had great numbers of cases of that sort.

3661. I need hardly ask you whether the Board are disposed to put in force those powers to prevent those nuisances?—They have not only a disposition but we have done it, we have given orders to all the lock-keepers to remove all dead animals, and all refuse that accumulates at those points. We generally find that all accumulations of floating stuff, whatever it may be, are arrested at the weirs, and the lock-keepers are supplied with very long rakes of a peculiar construction, and it is their duty to take those things out of the river, dig a hole in the towing-path, and bury them, and they have performed that duty.

3662. Do you know whether Mr. Simpson has made a section of the river just above the point where the Chelsea Waterworks take their water at Hampton?—No; I have not seen any section drawn by Mr. Simpson.

3663. You have no fear as to the abstraction of such an amount of water as may be necessary for the supply of the metropolis, have you?—Not the least fear in the world.

3664. And still less if the principle of storing were adopted?—No fear at all if the principle of storing were adopted at some point above the highest town, which you may, I think, fairly call Oxford, where there are some places where a large amount of storage could be made, and where the fall would be very great downwards, because the river takes a rise up there; and I should think that very large reservoirs, if necessary, could be formed for the storage of water in wet weather.

3665. I suppose that any sewage discharged into the river above Oxford would lose its chemical qualities before it arrived here?—One cannot quite get over the idea that when the water is running down the river at the rate of two or three miles an hour, and then runs over the tumbling bay and gets washed about, it becomes aerated and it loses an enormous quantity of foul matter that is held in suspension.

3666. (*Mr. Harrison.*) If necessary, do you suppose that Parliament would hesitate to extend the powers of your Conservancy Board beyond three miles?—I have no doubt that if Parliament considered it necessary they would do so; but three miles is a pretty long stretch.

3667. (*Sir J Thwaites.*) You have of course observed the condition of the Thames within the metropolitan area?—Yes.

3668. It has improved, has it not, very much all the way up?—Yes, wonderfully; there is no doubt about that. It is quite impossible to express the difference in the character of the water now compared to what it was nine or ten years ago, which is no doubt caused by the taking of the sewage away to another point.

3669. (*Mr. Harrison.*) Mr. Leach is your Acting Engineer, is he not?—Yes, he is.

3670. Has he made many observations extending over any length of time upon the Thames with regard to its flow?—Yes, a great many. We have got observations at every lock as to the height of the water every day, and below the locks we have observations at all the piers as to the state of the tide at high water and low water all the year round for the last seven years.

3671. I mean particularly as to the upper part of the Thames above Teddington?—Yes, he has those; the lock-keepers keep a register every day of the height of the water up there.

3672. (*Col. Harness.*) Is there any upward flow of water at all at Richmond during any period of the tide?—Yes.

Capt. E. Burstal, R.N.

23 May 1867.

3673. Where does that upward flow cease?—At Teddington lock; there is a little stream observable even at Twickenham. You get a stream sometimes at the rate of as much as half or three quarters of a mile up at Twickenham.

3674. Does the tide rise quite to the level of Teddington weir or about the level of Teddington weir?—I do not know the exact level of Teddington weir, but I think it is somewhere about 2 feet 6 inches or 3 feet above Trinity. I do not quite know what it is, but I know that there have been instances in which the tide has flowed over the top of Teddington lock, and really swelled the river at Kingston.

3675. (*Chairman.*) Could Mr. Leach give the Commission in detail the various gaugings of the river which you have mentioned?—I think it is very likely he could.

3676. (*Sir J. Thwaites.*) With regard to the arrangement with the water companies, that in consideration of certain steps being taken to purify the Thames each company should contribute 1,000*l.* a year; supposing any fresh source of water supply were established how would that contract stand as between you and the companies?—If the companies were done away with, and the water companies did not supply London, I suppose they would not pay us the money.

3677. Are they not under a statutory obligation to do so?—Yes, under the Act of 1866 they are, but of course if the water companies are done away with, it is quite clear we cannot get that contribution.

3678. (*Chairman.*) As I understand, they pay you 1,000*l.* a year each for certain things which you do on the river?—Their object is to keep the storage water, and we have to maintain the weirs and locks, all of which tend to keep up the water.

3679. It is for work done, and which is supposed to be for their benefit, that they pay you the 5,000*l.*?—Yes, for doing what we do towards maintaining the purity of the water.

3680. In the event of its being found necessary (supposing the supply of water for the metropolis is obtained from the Thames) to make either one or more very large reservoirs, which might be a very costly undertaking, the same argument would apply to induce them to pay an additional sum for such reservoirs in the same manner as they pay you now for the work done at the weirs?—I should think so, certainly.

3681. (*Sir J. Thwaites.*) Just reverse the question of contract as regards that payment of the water companies, supposing that they were compelled by Parliament to obtain a supply elsewhere, and supposing that Parliament were to make provisions for dealing with that water, what would be the position of your Commission, having certain obligations to discharge in consideration of this payment; would you be prepared to give up that payment and still discharge your obligations?—I cannot say what our Board would do, but, as I said before, if the water companies occupation is done away with, they would not have the means of paying us the 5,000*l.*, and we should have to do the best we could without it.

3682. (*Mr. Harrison.*) You will have to raise a considerable amount of money, will you not, to put your locks and weirs in order?—Yes, it is a very expensive thing indeed.

3683. And that money you will borrow partly on the security of this amount of contribution from the water companies?—Yes, that would be part of the security, no doubt.

3684. (*Sir J. Thwaites.*) The locks all the way up were in a very bad condition, were they not, when you took them in hand?—Very bad indeed; we are repairing some of them now; some of them are very dangerous indeed. We have three in hand at once now, putting new lock gates in. We are going to rebuild Bell weir entirely, and Romney lock entirely.

The witness withdrew.

G. W. Ewens, Esq.

GEORGE WHIFFEN EWENS, Esq., examined.

3685. (*Sir J. Thwaites.*) Are you a civil engineer?—I am not.

3686. What are you?—A merchant.

3687. Do you know anything about the supply of water to the metropolis—have you turned your attention to that subject?—In common with many other scientific subjects, I have studied that question a good deal. Some years ago, from having been brought in contact with the inquiries in reference to cholera, I was led to imagine that the supply of water had a good deal to do with it, and subsequent inquiries led me to seek for other sources than that of the Thames for the supply of the metropolis. My occupation and inclination led me in subsequent years to seek for those sources, and imagining from the tests that I applied to the water supplied by various streams that none of those streams were sufficiently pure for the supply of a great metropolis, I came to the conclusion that the really legitimate source of supply was that of springs, provided that those springs could be discovered that would give a sufficient volume for such a supply. After some years of hunting about I fancied that I had discovered springs of a sufficient volume, and I have had the water analysed by Dr. Hassall; he pronounces it to be exceedingly pure, and I am satisfied that the quantity is quite sufficient to supply the metropolis.

3688. Where are those springs?—The springs themselves are situated six miles south of Goodwood. I am obliged to bring my scheme before the Commission in a very unpretending sort of way.

3689. You stated that you were a merchant?—Yes, my own business is that of a merchant, but in common with a great many other scientific matters, I have looked into this and made a sort of hobby of it. I had the pleasure of forwarding you a report upon the subject.

3690. Where is the point where the springs exist?—The springs extend from Emsworth (about six miles from Goodwood) to Bedhampton in Hampshire, a distance of two miles. By a singular coincidence nearly the whole rainfall upon a large shed of upwards of 50 square miles finds an outlet there. A very large proportion of this watershed is composed of chalk hills and sandy valleys, receiving very little cultivation, sustaining a very small population, and, as a consequence, the water contracts very little contamination from either animal or vegetable organic matter laying on those surfaces.

3691. Will you describe the springs?—I have brought with me a very rough sketch of those springs (*producing a sketch*). These springs rise at Emsworth, Havant, Bedhampton, Brockhampton, and Langbourne, and they throw up enormous bodies of water.

3692. Do they rise out of the chalk?—Although the valley in which these springs take their rise is composed of a very strong clay, I imagine that as the hills above consist of chalk, so the chalk underlies the clay in the valley, and the water may find its way to the surface through fissures of the chalk.

3693. Have you gauged the quantity of water at a point near to Bedhampton mill?—I have repeatedly gauged the waste water from Messrs. Snook's mill, which is driven by the whole supply derived from the Bedhampton springs, and in August 1866 the quantity amounted to about 87,450,000 gallons every 24 hours during the summer of 1864, at which time I resided in the immediate neighbourhood. After an uninterrupted drought of *seven weeks*, the water of the whole of the springs decreased in volume 30 per cent., but not to any greater extent.

3694. Can you put in any result of your testings

for a series of years ?—The variation in the quantum thrown out at various times of the year is so small that I can only account for it by the water having such an ample depth of chalk to percolate through before it comes to the surface.

3695. Have you gauged those springs in every month of the year ?—Not in every month.

3696. Have you a memorandum of the gaugings and the result of each gauging ?—In August 1866 at the time that the water was measured, or at least this estimate was made, it was about the driest season in the whole of that year, and it gave me this result.

3697. Have you any other result ?—With the exception before mentioned, I have gauged it for the last five years repeatedly, at various times of each year, and the result has always come out so very near that the difference was almost imperceptible.

3698. Have you not observed any variation in the flow ?—Only as above stated.

3699. How many mills are there from the point of your gauging to the discharge into the sea ?—There are *six streams* formed by *nine separate* series of springs ; each of these streams flow into the sea at an average distance of half a mile from the spot from whence they take their rise. There are eight flour mills driven by these six streams, and I have generally gauged the waste water at the mill sluices when the mills were not working.

3700. Are they large flour mills ?—Four of them are very large mills.

3701. (*Col. Harness.*) Does the whole stream go through those mills ?—Supposing this and two following questions to refer to the Bedhampton stream, yes.

3702. (*Sir J. Thwaites.*) They are not overshot mills, I suppose ?—No, they are undershot mills.

3703. (*Col. Harness.*) Do you remember how many pairs of stones they work ?—I am not quite sure about that, I think it is five pairs of stones.

3704. (*Sir J. Thwaites.*) Have you observed any other spring in the neighbourhood ?—No ; this spring at Havant (*pointing to the sketch*) is what I have termed the waterworks spring for the supply of the town of Havant, which I have not included in this estimate.

3705. Then the supply of the town of Havant is exclusively taken from the town spring ?—The waterworks are built over a spring which, after supplying the district, leaves a surplus which forms the Brookhampton stream, and at 500 yards from its point of issue discharges 13,450,000 gallons every 24 hours into the sea. This spring is not included in what I call the town springs.

3706. Have you gauged the flow from the Havant town springs ?—Yes, it is 9,000,000 gallons every 24 hours.

3707. How often have you gauged it ?—Some scores of times.

3708. Do you find any variation ?—Except in the long drought of 1864, it has been so little as to be almost imperceptible at any time of the year.

3709. Now as to the Langbourne springs, of which there are three, what is the quantity obtained from those springs ?—9,000,000 gallons every 24 hours. Then there are two springs at Warblington which yield 4,500,000 gallons, and the Westbourne springs flowing through Emsworth yield 13,500,000 gallons.

3710. What is the distance between those several springs ?—It is two miles from Emsworth to Bedhampton.

3711. You have taken the volume of water in all those springs, except that which supplies the waterworks for the town of Havant ?—I have ; I have excluded the supply requisite for the district.

3712. What is the available quantity from all those springs ?—134,850,000 gallons.

3713. With the exception of taking the water from those mills, there is no other evil is there that would arise from the abstraction of the water ?—No; it only supplies the mills named, and then flows into the sea. All the springs could be tapped and brought to a point at Bedhampton, where a reservoir could be constructed.

3714. How far is the point of Bedhampton from the metropolis ?—64 miles as the crow flies.

3715. Have you formed any estimate of the cost of bringing that water to London ?—Yes, I have made inquiries upon that point.

3716. Not being an engineer, have you taken the opinion of any person who is competent to form a sound judgment upon the matter ?—Yes, I think so. To purchase the whole of the mills which possess water rights would require 50,000*l.*, and the subsequent value of those mills, that is to say with the water abstracted, supposing they were turned into steam mills, would be 40,000*l.*, leaving the cost of obtaining the whole water rights at 10,000*l.*, and my total estimate for the whole of the works until the water is delivered into the mains of the existing water companies in the metropolis is 1,280,000*l.*

3717. Whose estimate is that ?—Mr. Butter's, of Hackney, a large builder and contractor, and a man of great business capacity in matters of this kind.

3718. Then the deprivation of water rights you estimate at what ?—10,000*l.* ; and the cutting of a trench for two miles to tap all the springs, 20,000*l.* Of course the water will have to be raised to a certain level.

3719. What is the level of the point at Bedhampton ?—15 feet above Trinity high water in London.

3720. What fall do you give ?—I propose to pump the water into a reservoir at about the height of 180 feet.

3721. That would be a fall of 195 feet ?—Yes.

3722. (*Col. Harness.*) What is the distance of the reservoir from the place where you pump ?—I should say about a quarter of a mile.

3723. (*Sir J. Thwaites.*) Do you get a fall of 180 feet in a quarter of a mile ?—The proposed reservoir, a vast chalk quarry, is situated at the top of the eastern spur of the Portsdown hill, upon which the new line of forts are constructed, and at this point possesses an incline of about 40 degrees. This quarry, with little alteration, would contain 20,000,000 gallons.

3724. What is the cost of your culvert ?—My estimate for the works and machinery requisite for pumping so large a body of water into the receiving reservoir just named is 120,000*l.* ; the water could then be conducted in an open cutting 25 miles to the large fountain reservoirs situated amongst the chalk hills laying south and south-west of Petersfield, or to the immense sandy waste known as Woolmer Forest, which, at a cost of 10,000*l.* per mile, would be 250,000*l.*, and from the fountain reservoirs to Weybridge, a distance of 25 miles, in a substantial cemented conduit.

3725. What is the size of your tunnel ?—It would be 12 feet in diameter, at 15,000*l.* per mile, for 25 miles, costing 375,000*l.*

3726. What will you have to cut through there ?—Only chalk and sand.

3727. If you get into the sand you will have to concrete, will you not ?—Undoubtedly. I propose to make the principal reservoir between Petersfield and Liphook. There is a succession of chalk hills from Havant to that point.

3728. Are we to understand that from this reservoir at what you call your pumping station a quarter of a mile from Bedhampton, the water will flow by gravitation to the reservoir between Petersfield and Liphook ?—Yes. It is a matter of small importance as to the precise spot at which the fountain reservoirs are formed, because there are so many facilities for forming such reservoirs that the water may be stored to almost any extent in the said district.

3729. What height are you at your reservoir at Liphook above high water?—The volume of water discharged by the before-mentioned springs will form a stream 30 feet wide, 3 feet deep, with a flow of two miles per hour, and to give that velocity would require a fall of 18 inches per mile, and would leave an

G. W. Ewens, Esq.

23 May 1867.

elevation at the surface of the fountain reservoirs at Petersfield of about 160 feet.

3730. Starting from that point towards the metropolis, what line do you take?—After passing the Liphook station I should bring it past Godalming and Guildford to Weybridge, and then cross the Thames with one portion of it. I should divide the stream at Weybridge, and bring a sufficient quantity to Thames Ditton to supply the southern districts of London, and I should take a larger supply round to the north to Lea Bridge for the East London Company, the New River Company, the Chelsea Company, and other companies.

3731. How do you propose to supply the higher parts of the metropolis?—I think you will find that the elevation of the fountain reservoirs will be quite sufficient to discharge the water into the works of all the existing water companies in any part of the metropolis.

3732. You are, as I understand, 160 feet high at the reservoir, and you will consume part of that by your gravitating power up to the metropolis?—The weight of the water will carry it to the metropolis with only a loss of about one-third of elevation.

3733. When you arrive in London what height are you above high water?—If you take as a test the Croton aqueduct, near New York, you will find the fountain reservoir possesses an elevation of 166 feet above that city, at a distance of 38 miles from the distributing reservoir on the island, and requires a fall of 15 inches to the mile to give the water a momentum of $1\frac{1}{2}$ miles per hour, thus reducing the elevation of the water near the city to 119 feet, so that, allowing for greater speed and to carry the water into all the water companies works, we should still have a pressure equal to 50 feet of elevation.

3734. But when you arrive in London at Lea Bridge, is that your general reservoir?—No, that would be for the supply of the East London Company only.

3735. How do you propose to supply the western parts of the metropolis?—I propose to supply the west of London by the various existing companies.

3736. Your plan shows a line to the East London Waterworks station, and that you say is for the supply of the eastern district; how do you propose to supply the western part of the metropolis; where would your reservoir be for that supply?—I do not know that to deliver the water into the pumping works of the existing water companies would require another reservoir, but if it should be so, a distributing reservoir for the western districts could be formed at Wormholt Scrubs, and thence distributed to the Chelsea, Grand Junction, West Middlesex, New River, and East London Companies, and supplied by them through the existing system.

3737. You would not carry it down to the east and then carry it back again to the west?—Certainly not. Starting from the division of the conduit at Weybridge, the supply necessary for the whole of the Middlesex side of the river I should carry as near as possible to the works of the existing companies and deliver into their works up to the extreme point of requirement, that of the East London Company at Lea Bridge.

3738. You have not indicated any line?—I thought it scarcely necessary to do so.

3739. When you have arrived at Lea Bridge, in order to bring the water towards the western part of the metropolis, you will have to pump it again, will you not?—The water carried to Lea Bridge will only be that required for the supply of the eastern district, and at this point there will be a sufficient pressure without pumping to carry the water over the whole of the East London district.

3740. Of course your channel is not under pressure, because you have an open cutting?—The only portion of the distance the water will be conveyed in an open cutting will be before reaching the fountain reservoirs at Petersfield, as the water will be conveyed by a substantial conduit from that point, and as that conduit would be at such an elevation that from the surface of the lakes to the level at which the water would cease to flow through the conduit would of course give a pressure of many thousands of millions of gallons, because a depth of 100 feet might be given to these lakes if necessary.

3741. Then the channel is not under pressure?—Not before reaching the fountain reservoirs, but afterwards, yes.

3742. Do you mean to say that you will have 180 feet of pressure at the point where you describe this reservoir to be situated in Woolmer Forest?—No, 160 feet.

3743. And will you go in a covered tunnel all the way from that point to the metropolis?—Yes, all the way.

3744. By iron pipes?—Either by iron tubes or strongly constructed conduit.

3745. And you put those pipes under the pressure due from 180 feet of elevation, is that so?—There would be of course some means of regulating the flow of the water through that conduit.

3746. You have probably not directed your attention to that point?—My view of the matter was, that the existing companies should be allowed to take this supply of water, and to distribute it according to their present arrangements, so as not to interfere with their already vested interests.

3747. (*Col. Harness.*) You idea is to carry the water by a proper aqueduct past the works of all the London Water Companies up to the most eastern district, and as you pass to give it to those companies?—Yes, decidedly. At Thames Ditton I propose to give them a sufficient quantity for the southern district and let them pay for it, and then to bring the remaining portion across the Thames to supply the northern district.

3748. And you would deliver it to them from the altitude that the water in your aqueduct would have at the point at which they take it?—Yes.

3749. And it will be for them to utilize it?—Yes.

3750. (*Sir J. Thwaites.*) What is the entire cost of your scheme, including the reservoirs?—1,280,000*l.*, and that is a sum which those companies could raise amongst themselves. The whole scheme will not require more than half the amount required for the recently constructed works at Glasgow.

3751. Have you had any analysis made of the water?—The water is simply pure. This is Dr. Hassall's analysis of the water (*producing the same*).

3752. When was that made?—On the 19th of October 1866.

3753. Will you put that table in?—Yes. (*The witness delivered in the following table*):

RESULTS of the ANALYSIS of a SAMPLE of WATER received from MR. EWENS, October 12th, 1866:—

Constituents of an Imperial Gallon.

	Grains.
Carbonate of lime	13·82
Carbonate of magnesia	1·03
Sulphate of lime	·42
Sulphate of potash	·67
Sulphate of soda	·35
Chloride of sodium	2·00
Silica	·68
Alumina and iron	·44
Nitric acid and ammonia	none
	19·41
Matter destroyed by heat, partly organic matter	1·04
Total solids	20·45

The oxidizable organic matter in this water is but small, and much less than is contained in the water with which London is now supplied. On the whole this water may be said to be a pure and wholesome water.

ARTHUR HILL HASSALL, M.D.,
Author of "The Microscopical Examination of the Water supplied to London;" of "Food and its Adulterations."

3754. (*Mr. Harrison.*) What is the degree of hardness of the water?—In its present state about 14

degrees of hardness. But if the Watford water, the component parts of which nearly approaches this water (except its organic matter) can be reduced by Clark's process from 17·45 degrees to 2·74, so this water, containing a smaller amount of lime salts, could be raised to a higher standard than that of Watford.

3755. (*Mr. Prestwich.*) This is very similar to the New River ordinary chalk water, is it not?—In point of inorganic matter it is.

3756. It contains carbonate of lime nearly 14 grains. What degree of hardness did you say it was by Clark's test?—In its present state about 14 degrees, but by Clark's softening process it could be reduced to less than seven degrees.

3757. Is it not more than that?—Not as compared with the Watford water.

3758. You have not come to that conclusion by the test?—No; Dr. Hassall did not give me that. I only arrived at that by comparison with other waters.

3759. Do those springs rise in the chalk?—The water is no doubt thrown up from fissures in the chalk, although the valley is composed of a stratum of heavy solid clay many feet in thickness.

3760. But the clay in the neighbourhood of Havant is London clay, which overlies the chalk; you do not come to clay at the base of the chalk?—I had an idea from its purity, gravity, and colour that it more nearly approached the Poole clay, and that this valley was an extension of the same basin; however that may be, we should find this clay, which extends more or less from Bishop's Waltham to Littlehampton, over the whole of Hayling and Thorney islands, and inland to Haslemere, exceedingly useful for making bricks for the works.

3761. At all events it would be the tertiary clay overlying the chalk. Have you any well in that district which traverses the chalk and reaches the clay beneath it?—Yes; I had a pump at Warblington, where I lived, and this well went through a thin layer of gravel and chalk, and then down to this bed of clay upon which the water rested.

3762. You would not have a thin bed of chalk under those circumstances; the chalk in that district is exceedingly thick, is it not?—Undoubtedly chalk forms the base of the district. The thin stratum mentioned very closely resembled chalk, and was used as a substitute for it to mix with clay in the manufacture of bricks.

3763. I think you are wrong, because the chalk dips again beneath the tertiaries and between there and the sea; it is merely a ridge of chalk?—It may be so. On that particular spot I know I am right, but it may not be so as a rule.

3764. I believe you will find that the chalk there is several hundred feet thick; however, that would be immaterial to your argument. You state that there are springs here of a certain volume which issue probably from fissures in the chalk, whatever may be the position of the clay with regard to the chalk?—Exactly so.

3765. The first of those springs you have gauged at 87,000,000 gallons?—Yes, the first set of springs at Bedhampton.

3766. And those gaugings you have conducted at infervals of several weeks?—Yes, for five years.

3767. How have you made the gaugings?—I have made inquiries of the millers as to the weight of water required to drive their mills, and the number of hours they can drive their mills from those springs; that is one way. Then where the water has been confined within a channel, I have measured the width, and depth, and velocity with which that water is constantly flowing when the mills are not at work; that is to say, the waste water, and from those calculations I think I am considerably under the mark. I have allowed a margin for contingencies, but I imagine that the water amounts to really, in fact, 150,000,000 gallons per day. I have therefore left a margin of 16,000,000 in case of an error. I may here say that should not this quantity be sufficient, although nearly double the present supply, another 50,000,000 can be added by absorbing two streams near Petersfield, and over or near which the conduit would have to be carried. The water is equally pure, and would bring the total to 200,000,000. There are also means of very considerably increasing even this quantity.

3768. Is no use made of those springs except for the supply of the mills and the town of Havant?—None whatever.

3769. They are not used for any water supply?—Only for the supply of Havant from the existing waterworks.

3770. The channel by which you would carry the water from the neighbourhood of Havant to London passes first through the chalk ridge of the South Downs?—Yes; it would be raised to a very large reservoir, which has been excavated for a great number of years, at the side of the hills on the eastern spur of Portsdown hill, at Bedhampton.

3771. Should you not have to carry it through the Downs the greatest part of the way through a tunnel?—I think it might with perhaps a little tunnelling be carried by means of an open cutting the greater portion of the distance from this first reservoir to the lakes or fountain reservoirs I should propose to form near Petersfield, in the neighbourhood of which the water could be stored to any extent.

3772. You pump it to a height of about 190 feet, but that height would not be sufficient to carry it over the South Downs without tunnelling?—Perhaps not entirely without; as near as I could judge, about three miles of tunnelling through the chalk, allowing a gradient of about 18 inches per mile, or a velocity of two miles per hour, to the water.

3773. And from Petersfield to Guildford you traverse a district which for the main part consists of sand?—Yes.

3774. But there are sands through which you will have to carry the water either by pipes or by a channel, which would have to be cemented?—Precisely so; as far as Weybridge, I apprehend.

3775. When you cross the Thames at Weybridge, at what height should you cross it?—At Weybridge, where it is proposed to divide the supply, we should have an elevation of about 130 feet; and I think if the water were conveyed from the junction to the Thames, a distance of about two miles, by means of iron tubes, the level might be so depressed as to allow the aqueduct over the river to be constructed at, say 30 or 40 feet.

3776. Your object would be merely to deliver it to the reservoirs of the companies in London at their present level?—The water companies seem to be entirely at a loss to find a pure supply of water at such a cost as to enable them to obtain it, and my object is to direct the attention of the Commission to this supply, and by such measures as may be deemed advisable to enable the existing water companies to raise amongst themselves the capital required to convey this water into their several reservoirs, and from thence supplied to the metropolis by the existing service system; by this means the invested interests in the water companies, amounting to many millions sterling, will be protected, good dividends will still be paid without increasing the present water rates, which must be a necessary consequence on the adoption of any more expensive scheme.

3777. Then you would have a very great fall from Woolmer Forest to London?—Yes, a fall of about 160 feet; and provided the fall was economised by having a sufficiently strong conduit to bear the pressure, we could carry it into the highest reservoir in London.

3778. (*Mr. Harrison.*) Your scheme involves pumping at Havant?—Yes.

3779. And you would deliver it to the water companies at a level from which they would have to pump it again?—Yes, except in the case of the Lambeth, Vauxhall, and East London Companies, who would have sufficient pressure to carry it over their several services.

3780. But you propose to make your reservoir at

G. W. Ewens, Esq.

23 May 1867.

Woolmer Forest 160 feet above ordnance datum?—Yes.

3781. What fall would you calculate per mile from that to London?—18 inches per mile would give the water a velocity of two miles per hour.

3782. For how many miles from Woolmer Forest to London?—Supposing the reservoir to be at Woolmer Forest, which is just below Liss, it would be 38 miles to Charing Cross.

3783. Taking it at 40 miles, and says 18 inches fall per mile, that would reduce your head of water in London to 100 feet above ordnance datum?—About 100 feet.

3784. Are you aware that there are a great many houses in London which are 200 feet above ordnance datum?—I imagine there are some houses which are over 200 feet above ordnance datum, but my object was not to bring a sufficient pressure upon this water to carry it to that altitude, but to leave it to the present companies to make use of their present machinery.

3785. In point of fact your scheme involve, first, lifting the water by pumping at Havant, and a second lifting by the water companies in London?—Yes, except in the case of the three companies named.

3786. Can you get over the country without raising it?—Yes, we could get over it by a syphon from Havant, and deliver it to the present water companies without any artificial lifting between that point and London.

3787. What is the level of your springs at Havant?—15 feet above Trinity high water.

3788. I think you must be mistaken in supposing that you could deliver it by a syphon?—Not from that point. I am speaking now of taking it from the reservoir at Bedhampton on the Down hills.

3789. You must have one pumping at Havant to get to the reservoirs, and when the water gets to London you require another pumping?—Just so.

3790. Do you imagine that the water of those springs does not come from the chalk?—The watershed embraces at least 50 square miles, for the most part consisting of chalk and sandy surfaces, through which it percolates until finding an outlet in the valley.

3791. What is there to make this water different from ordinary chalk water?—It is not essentially different, the only difference is that it contains no organic matters. Its component parts are similar to the Watford water, with the exception that it contains no organic matter or acids of any description.

3792–3. (*Mr. Prestwich.*) You say that it contains no organic matter, the analysis does not bear that out, does it? The matter destroyed by heat, partly organic matter, is 1·04; that would indicate a certain quantity of organic matter, would it not?—I imagined from what Dr. Hassall's assistant told me, that it was comparatively free from organic matter. I imagine that the water which was taken for this test was perhaps hardly a fair sample, it was taken from one of the streams running from the springs. The streams running from the springs would naturally contain animal life of some kind or other, and I fancy a small amount of organic matter may have been found in the stream which would not have been found in the water at the spring head.

3794. It is not a large amount at all events?—No. The principal objection to the water, of course, is the lime which it contains, but there is no more lime in it than there is in all waters supplied by the chalk, and it could be reduced by Clark's process to two degrees of hardness. I might say that my total estimate includes 25 miles of cemented aqueduct reaching from Weybridge to Lee Bridge.

3795. Those springs I presume are well known in the district?—Yes, very well known.

3796. Has it been ever considered to use them for the supply of Portsmouth or any of the adjacent towns?—I have considered it, and intend, provided the supply is not thought sufficient for the metropolis, to endeavour to obtain powers to carry it coastwise to supply Portsmouth, Gosport, Chichester, Littlehampton, Worthing, Brighton, Eastbourne, and Hastings, which towns are very badly supplied with water.

The witness withdrew.

Adjourned to Wednesday next at 11 o'clock.

Wednesday, 29th May 1867.

SIR JOHN THWAITES IN THE CHAIR.

Alderman SIR BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS.	JOSEPH PRESTWICH, Esq.

A. Bain, Esq.

29 May 1867.

ALEXANDER BAIN, Esq., examined.

3797. (*Chairman.*) What position do you hold?—I am Professor of Logic in the University of Aberdeen.

3798. We understand from a letter which you have addressed to his grace the Duke of Richmond that you have given considerable attention to the question of water supply?—Yes, owing to my having been assistant secretary to the Metropolitan Sanitary Commission and then to the General Board of Health, and having also been on an intimate footing with a number of scientific gentlemen who have investigated this question, I may say that my knowledge is pretty intimate as to the course of inquiry for a certain number of years. It was on those grounds that I chose to intrude myself on the Duke of Richmond, and not as being entitled to speak before the public with authority as to the conflicting schemes.

3799. Your letter points to two sources of supply, one of which is the Watford chalk?—Yes.

3800. Upon which a considerable amount of discussion took place in the years 1850 and 1852?—Yes.

3801. And it also points to the Bagshot sands?—Yes, I am well acquainted with the course of official inquiry on both proposals.

3802. You refer to the purity of the water from those two sources. Have you paid any attention as to the volume of water which could be obtained?—Of course I was perfectly aware of the nature of the evidence that was presented to the Board of Health. The Board chiefly took up the Bagshot scheme. It was I may say their scheme. I know what their evidence was, and I also know what the evidence has been with regard to the Watford supply; at least I know the documents and authorities that gave that evidence.

3803. That was in 1850, I believe?—Yes, the Inquiry and Report of the Board of Health was in 1850.

3804. Can you give the Commission any information as to the quantity of water obtainable from the Watford source?—Of course I am not prepared with the exact documentary evidence that I could furnish if I were to be asked to do so; in fact I did not know exactly what things the Commission would ask me, therefore I am not prepared with any specific documentary evidence. I can tell, by referring to the Report of the Chemical Commissioners, what opinions were formed on the subject at the date of that Report.

3805. You are probably aware that the quantity of

water is a question of great importance in this inquiry? —I am aware of that, but I was not aware that the Commission would expect me to give any information upon that point. I should require a few days to refer to the evidence or to find out the parties. Of course there are parties much better able than I am to give that evidence.

3806. You speak in your letter of certain inquiries having taken place and certain reports being presented to government and to parliament, and you are surprised that the public have not paid more attention to these reports?—Yes, certainly.

3807. And surprised that this inquiry should now be instituted in the presence of those reports?—Yes, that is quite the case.

3808. One would naturally suppose, therefore, that you had paid attention not only to the quantity of the water which it is ascertained could be obtained from those two sources of supply, but also the quality?—Of course I have paid attention to the evidence given by gentlemen who are entitled to speak upon that point. I have before me the report of the Government Commission of 1851.

3809. Can you tell us from the evidence of those gentlemen as to the quantity of water obtainable from the Watford scheme first?—I can refer to the report of the Chemical Commissioners appointed by Sir George Grey in 1851, who were Mr. Graham (now the master of the Mint), Professor of Chemistry in University College, Dr. Miller of King's College, and Dr. Hofmann. Those were the Commissioners, and if the Commission choose I will read the questions that were put to them.

3810. Were any other than chemical questions referred to them?—Yes, the question of quantity was referred to them as to both sources; they had referred to them the question of the present supply, the Bagshot supply, and the Watford supply, and the evidence as to the quantity. The report is signed by Mr. Graham, Dr. Miller, and Dr. Hofmann, Sir George Grey's letter being dated the 23rd of January. The passage in which they speak of the quantity is this short sentence. They say, "The proposals of the "London (Watford) Spring Water Company" (whose water was referred to them) "extend only to a daily "supply of about 8,000,000 gallons." That was the proposal of that company. "But the area of land "sloping towards Watford, and consisting, for the "most part of chalk hills, embraces more than 1,200 "square miles, and is estimated by Mr. Homersham, "the engineer of the company, as equal to a daily "supply of 408,000,000 gallons, the quantity of "water which reaches the lower fissures of the chalk "being calculated at one half of the rainfall." That is the calculation, and they go on to give another fact, quoting Mr. Stephenson's original report of 1840. "A well sunk in Bushey meadows in 1840, "when this source of supply was first recommended "by Mr. Robert Stephenson, has been found capable "of yielding, by pumping, 1,800,000, or nearly "2,000,000 gallons per day;" and then they give the particulars of the well. That was from one well, which was used as an experiment of what could be got. The detail is given of the construction of the well. "This well is 12 feet 6 inches in diameter at "the bottom, and 34 feet deep, with four small bore "holes, 5 inches in diameter, descending 130 feet "below the surface of the ground."

3811. Are you aware whether that district has been additionally taxed since then, or whether it is equal to the yield referred to by the Commission?—No, I cannot undertake to give evidence upon that point; indeed, I am merely repeating the evidence that was given in 1851.

3812. And now, as to the question of the purity of the Watford water, what was the opinion of the Commissioners?—Upon that point the Commissioners speak very decidedly, because they speak from their own personal investigation, and this is their statement of the general character of the supply:—"First, the "spring water contains no matter in suspension to "cause turbidity or colour; its clearness and brilliancy "are unexceptional. 2. It possesses a desirable cool- "ness, having at all seasons a temperature between "50 and 52 degrees. 3. The amount of organic "matter it contains is inconsiderable, and of a kind "which appears to be incapable of undergoing putre- "factive decomposition, so that it may be safely dis- "regarded. 4. The salts which it contains would not "interfere with its use as a beverage. It is, indeed, "a choice water for drinking. 5. The great and "obvious objection to the chalk spring water is its "hardness, which, when the water is first drawn, is "uniformly very nearly 18 degrees, or 4 degrees "harder than the present metropolitan supply. "The weight to be assigned to this objection, how- "ever, appears to be much reduced by the following "considerations," and then, with regard to this, they go with some minuteness into the process invented by Professor Clark, of Aberdeen, for softening or reducing the hardness, a process which they completely investigated, and on which they pronounce a very decided opinion in another part of the report. In conclusion, they say that "the chalk spring water, after being "softened, is an extremely pure water. It appears "to be considerably superior even to the soft water "from the stream of the Surrey sands."

3813. Do they get rid entirely of the hardness?—Not entirely. They reduce it to two or three degrees, but it then stands comparison with the very softest waters of the country. "It appears to be considerably "superior even to the soft water from the streams "of the Surrey sands. The chalk water alone is "uniform in its excellence at all times, the sources "of it lying beyond the influence of weather or "season. In the judgment of the Commissioners "this softened chalk water is entitled, from its "chemical quality," (that is a point on which their authority is pre-eminently high) "to a preference over all others for the future supply of the metropolis."

3814. (*Sir B. Phillips.*) Is there any reference made there as to the cost of that softening process?—No, I think not; but, of course, as the process is in operation, it would be very easy for the Commission to get that information from the parties who have put the process in operation.

3815. (*Chairman.*) Is that degree of hardness, 18 degrees, the mean, or is it the maximum?—It is a steady water; it is the nature of spring water to have great steadiness.

3816. (*Mr. Harrison.*) Have you had any experience yourself of Professor Clark's process upon a large scale?—I have seen it in operation.

3817. At Watford?—No, it never was introduced into Watford; the Watford Company never was carried out.

3818. Where have you seen it in operation?—I saw it at Plumstead, near Woolwich, where it was in operation for a number of years.

3819. (*Chairman.*) Were those Davis' waterworks? —I suppose so. However, those waterworks have since been bought up by the Kent Company, and they use the chalk-water, but without softening. The process has been introduced into various other places. It has been in operation for a number of years at Caterham; and Caterham water represents a fair average example of the chalk-water.

3820. Do the Commissioners refer to the rainfall on the Watford district?—They make a reference to the rainfall.

3821. You state, did you not, that the quantity referred to was one half the rainfall?—Yes, that is the basis of the calculation.

3822. That one half the rainfall finds its way to this chalk basin?—Yes, it is supposed to do so.

3823. (*Mr. Harrison.*) You do not give any chemical opinion, do you, of your own knowledge?—I am not a chemist. I have gone through a considerable range of scientific studies, and I believe that I have some capability of estimating scientific evidence, but I am not a practical chemist, and never was. Of course the Commission can refer to Mr. Graham or any of those chemical gentlemen upon those points.

A. Bain, Esq.

29 May 1867.

3824. (*Chairman.*) Can you give the Commission any evidence of the Bagshot water, first as to the quantity, and secondly as to its quality?—Of course if I had an opportunity of referring to the report of the Board of Health I could very easily give you the exact points, but I now merely speak from memory.

3825. Did those three professors examine the water of Bagshot?—Yes, they did. Their results are in the Report before me. They first give the examination of the springs from the Bagshot sands, taking six selected springs, of which they give a very detailed analysis. The detailed analysis is cumbrous, but they give also a separate statement of the degrees of hardness. The six springs taken together represent an average hardness of 2·18 degrees. They remark that "those springs therefore exhibit an average "hardness of a little more than 2 degrees" which undoubtedly is very soft water; it is one of the softest waters that can be had. And then they state "the "value of this extreme purity and softness is not di- "minished by the other mineral and organic consti- "tuents of the waters which are insignificant in "quantity, and really of no account." They farther remark that "the nearly entire absence of carbonic "acid from these waters to which attention has been "drawn by Mr. Napier, is perhaps their most singular "chemical feature," so that they have a very decided opinion as to the quality of this water, and anybody who has been in the neighbourhood would say the same thing. I have myself known some of those springs; I happen to have lived at Moor Park; and in the grounds of Moor Park there is a well or a stream issuing from a cave called Ludlam's cave, the water of which was examined carefully by Professor Clark, who is the great authority on water. He pronounced it the softest water that he had ever examined: so that in fact the quality of these waters, or at least of these springs, is of a very high order. Then the Commissioners go on to speak of the quantity. "The question, however, arises how "far these springs represent the large supply of "upwards of 20,000,000 gallons which it is proposed "to draw from this district." Speaking from recollection, I understand them to refer to the quantity named in the report of the Board of Health, who alleged in their report, that they could procure 20,000,000 gallons of that exceedingly fine water. Of course the Commissioners visited the district and made a personal inspection to verify the statement which the Board of Health made upon the inspection of their officer, and they say in their report, "The visible springs are not very numerous, "nor did the yield of each appear very great. The "water from the largest might be carried off by a "two-inch pipe. It is proposed," (quoting from the Board of Health) "'to lead away the deep springs "only' extending 'the shallow land springs and "surface drainage.' The possibility, however, of "keeping these different waters separate appeared "to us extremely doubtful. The high ground consists "entirely of beds of siliceous sand, rarely indurated to "any extent or converted into sandstone which "constitutes enormous storing reservoirs for the "springs." I understand them to say that they are not indurated into sandstone so as to be retentive. "The springs are at all levels and a partial outfall of "water may take place at any point on the declivities, "and is not determined to a certain line, either hori- "zontal or vertical by the occurrence of a retentive "stratum, such as a bed of clay or rock along the "outcrop of which spring water might be collected," (that seems to be with regard to the difficulties of gathering it), "hence the slightest cause may occasion "the loss of a spring and its reappearance at another "point of lower level—from few or more of these "springs can the flow be accurately gauged, and it "was not attempted by the Board's engineer, Mr. "Rammell, to the gauging of the small streams or "rivulets even. Mr. Rammell observes, 'an insuper- "able obstacle,' was found 'in the porous nature of "the beds of these streams which rendered all "attempts to intercept or divert the whole of the "flow hopeless. From this cause it was quite im- "practicable either to draw up the water effectually "or to lead it along an artificial channel laid at a less "inclination for discharge into the box (in which the "water was to be measured); most of the smaller "streams have beds of perfectly clean gravel through "which, on the current being arrested, escape imme- "diately takes place. It appeared, indeed, on close "examination, that even the ordinary run of these "streams is not wholly over or above the surface, but "partly within the bed of the channel itself, much of "the water thus passing away insensibly between the "pebbles. Any attempt to dam up these streams "with a view to gauging over a weir must have "failed from the same cause." Those remarks are to show that they consider the quantity of the supply a matter of entire uncertainty.

3826. The calculation is that it would yield 20,000,000 gallons per diem?—The Board of Health calculated that.

3827. But that is not certain?—No.

3828. No reliable gauging was made?—No, and the difficulties of collecting are also alluded to.

3829. (*Mr. Harrison.*) Living as you do in Aberdeen, you have of course had an opportunity of putting some value upon the soft water which you there use?—Yes, no doubt.

3830. If my recollection serves me rightly, your water is about as soft as any in the kingdom?—I think it is about as soft as any.

3831. (*Chairman.*) It is the granite water, is it not?—Yes. It is the water from the granite high up the country.

3832. (*Mr. Harrison.*) Should you consider that if chalk water were supplied to London it would be necessary to soften it by Clark's process?—That water, I apprehend, has very decided merits independently of Clark's process, and of course those merits can be judged of from the very great range of towns that are now supplied with it; but then there is no doubt that this addition, as the Commissioners say, takes away the one great cause of objection; and with that, I think, the Commission may safely say (at all events it is the opinion of those chemical Commissioners) that the water is equal to any supply in any place.

3833. With your experience, if you had the option of supplying a town with that chalk water, or with such water as Aberdeen is supplied with, to which should you give the preference?—I would not undertake to give a preference without a full investigation of the two cases; but I apprehend that the chalk supply is really perfect, that is to say, no objection can be urged against it. I do not mean to say that a water might not be found one degree softer or two degrees softer.

3834. You have referred to Moor Park, are you aware that that is the residence of Mr. Bateman, the eminent engineer?—Yes, I understand that it is so. I was there long before he purchased it; I have merely a recollection of that well, which is a very remarkable one.

3835. Perhaps you may not be aware that since Mr. Bateman has resided there he has been to the expense of bringing that soft water, to which you have referred, to his own house?—I believe that Dr. Clark advised a former occupant of the house to do the same thing.

3836. Could you offer to the Commission any decided opinion as to the real value of such water as you have at Aberdeen over hard water?—Of course it is now well understood what the precise advantages of softness are; these have been recognized and admitted ever since that discussion began. First and foremost, with regard to washing, the economy is very great in soap and in labour. Then there has been, at various times, a good deal of testimony given as to the culinary value of soft water; for example, as to tea, there can be no question at all as to the great superiority of soft water. It has also been said to possess advan-

tages in respect to other culinary preparations; but the evidence is somewhat conflicting, and, therefore, I would not put stress upon any other points, as far as my own knowledge goes, except washing and tea. The washing interest is a very large interest, and in the first evidence given with regard to the softening process, which was Dr. Clark's own evidence before the Health of Towns Commission, he gave a computation of what he considered the saving of soap from the use of soft water.

3837. I gather from your view of it that you would prefer chalk water, you having the means of making it soft if you wished it?—So far as my knowledge has gone, that seems to me to be a perfectly satisfactory supply. I do not mean to say that a full comparison might not show advantages in another supply.

3838. In your letter you state the fact that injurious effects have been discovered from the supply of water to Glasgow from Lock Katrine?—I did not exactly intend that, but what I meant to say was, that there were certain scientific men who expressed misgivings or doubts about the perfect purity of the water in point of organic matter. That is a point so exceedingly subtle that it is the hardest thing possible to get very decided evidence upon it when it is not a broad apparent fact. One thing is certain, that you must combine with the chemical examination, a microscopic examination in the hot months.

3839. You do not give that as a matter based upon any actual experience, but merely as a matter of opinion?—I merely say that such opinions have been entertained by scientific persons; you are aware that those measures are all canvassed by opposing parties.

3840. (*Mr. Prestwich.*) There is a new supply to Aberdeen is there not?—Yes, there is a supply taken higher up the Dee.

3841. And that water is perfectly soft?—It is the same as the former with regard to softness, and it has the advantage of greater purity as regards mud or sediment.

3842. Have you ever heard of any objections raised to the use of soft water there?—Never; probably you allude to the question of the action of the water on lead.

3843. Or from its taking up organic matter with greater facility than hard water, or from any cause whatever?—No, I am not aware of any complaints. The question of the action on lead has been a matter of chemical investigation, and the results of that can be obtained if necessary.

3844. As far as regards that, it is a perfectly satisfactory supply?—Yes.

3845. (*Chairman.*) Is it an intermittent supply or a constant supply?—It is a constant supply.

3846. How long has that constant supply been in operation?—The date of the supply which has just been superseded is about 1830, to the best of my recollection. That was upon the principle of constant supply, and the new supply continues the same.

3847. Therefore it has been 37 years in operation?—It must have been that time.

3848. To your knowledge has any inconvenience arisen from the constant supply?—I am not aware of any.

3849. Have there been any complaints as to the waste by the consumers?—Last year, just before the new supply had come in, and when the town was dependent upon the old supply, which had become insufficient, there was a great scarcity of water; and at that time people indulged in comments upon the inhabitants in some of the lower districts carelessly allowing the taps to run; but until the town generally began to feel the scarcity, they made no remarks about it. The present supply is above all possibility of shortness.

3850. Do you know the system of supply to the poor, have they any cisterns, or simply a tap?—I rather think that in the poorer class of houses there are no cisterns.

3851. Are there standcocks?—Yes, there are standcocks in the streets.

3852. (*Mr. Prestwich.*) What is the supply per head at Aberdeen?—I am not sure that I can give the estimate offhand upon that point.

3853. There have been several reports, have there not, published upon the supply from the chalk from the Watford wells?—I am aware that there have been reports subsequent to the report of the Chemical Commissioners.

3854. The experiments at Watford were conducted for some considerable time, were they not? I mean the pumping apparatus?—The experiments of Mr. Stephenson are given in his report of 1841, which I have now before me, but I understand that the reasoning as to the Watford supply depends upon the computation of a good many different wells that are used for local purposes.

3855. Are you aware of the effect which that pumping and those experiments at the well produced upon the flow of the river?—I cannot answer that question.

3856. Do you know the maximum quantity that was pumped?—No, I cannot undertake to give the Commission the precise quantity.

3857. Nor are you probably aware of the gauging of the river Colne at the lower part of its course after it receives all the chalk springs of that district?—No.

3858. You state, do you not, that the hardness of the water could be reduced by Clark's process to two degrees?—I should not have mentioned the precise figure because that is somewhat a variable limit. In the most favourable waters it comes down to from two to three degrees, but it has not been brought as low as that in all cases. I would again respectfully state to the committee, that I do not consider myself as an authority upon this question. I speak merely from official and other means of being acquainted with the previous inquiries, and as in some degree competent to bring before you the facts which other men have given. I cannot undertake any personal responsibility in advising the Commission.

The witness withdrew.

WATERWORKS constructed under the direction of Mr. S. C. HOMERSHAM, Civil Engineer, to supply SPRING WATER softened by Dr. CLARK'S process.—June 7th, 1867.

Name of the Works.	Date when Works were opened.	Hardness of the Spring Water.	Hardness of the Spring Water softened.	Solid Contents of the Spring Water.	Solid Contents of the Spring Water softened.	Source of Supply.	Observations.
		Degrees.	Degrees.	Grs. per Gal.	Grs. per Gal.		
Plumstead, Woolwich, and Charlton Consumers Pure Water Company.	Augt. 1854	21	7½	31	18¼	Spring water from the chalk formation	These works were specially examined by order of the Government and favourably reported upon in 1856 by the late Henry Austin, Esq., C.E., Chief Superintending Inspector of the General Board of Health, and the report printed by order of Parliament. The works were purchased from the original company in 1861 by the Kent Water Company. When the works passed into the hands of the Kent Company, to the great annoyance of the consumers, the Kent Company ceased to soften the water by Dr. Clark's process.
Castle Howard, Yorkshire.	Octr. 1858	22 1/10	4 3/10	29¼	10¾	Spring water from the oolitic formation.	
The Caterham Spring Water Company.	Augt. 1861	18¾	3½	26¾	9¾	Spring water from the chalk formation.	
Herbert Hospital Water Supply.	Augt. 1865	21	7½	28½	—	Spring water from the chalk formation, supplied by the Kent Water Company.	Constructed for the Government, and by order of the War Office.
The Chiltern Hills Spring Water Company Limited.	Expected to be opened July 1867.	13¾	2¾	20¼	8¾	Spring water from the chalk formation.	

NOTE.—One grain of chalk dissolved in a gallon of water is one degree of hardness. In like manner four grains per gallon would produce four degrees of hardness, 10 grains 10 degrees, and so on.

Dr. H. Letheby.

29 May 1867.

Dr. HENRY LETHEBY examined.

3859. (*Chairman.*) You are, I believe, Professor of Chemistry in the London Hospital, and also Medical Officer of Health to the Corporation of the City of London?—Yes, I am.

3860. Your attention has necessarily been directed to the supply of pure water and to the effects of impure water?—Yes, very much so, not only in London, but also in most of the large towns of England.

3861. Can you give us any information as to the present condition of the water supplied to the metropolis?—Yes, I think I can. I may say in the first place that I have examined the water of the East London Company from the year 1861, twice every month until the present time, that I have made similar analysis of the water supplied by the New River Company every month from the year 1863, and a like analysis every month of the Kent water from that time, and in the year 1864 I was requested by the Medical Officers of Health of London, associated as they are under the name of the Metropolis Association of Medical Officers of Health, to make an analysis every month of the water supplied by the whole of the metropolitan companies. Those results have been regularly published.

3862. Can you put in the results of those analyses so made?—I can put before the Commission the results of the analyses in a general way.

3863. Do you know the general properties of the water supplied by the metropolitan companies, first from the Thames Waterworks above Hampton, the West Middlesex, the Grand Junction, the Southwark and Vauxhall, the Lambeth, the Chelsea, the New River (Lea springs and wells), and the East London?—Yes, that comprises all except the Kent Water Company, which supplies a very small portion of the metropolis?

3864. Is that water taken from the Ravensbourne?—It was formerly; it is not now; it is taken entirely from wells; not a drop is taken from the Ravensbourne.

3865. You think there is none of the Ravensbourne water in it?—None whatever. I suppose they have eight or nine wells, and they take the whole of their water from them. You will see that the first of these tables which I will hand in represents the general properties of the waters supplied to this metropolis in the month of January last, and it will be important to compare the results with the analyses made in the corresponding month of 1856, at the instance of Mr. Cowper who was then at the head of the Board of Works, and also the results of a like inquiry that was instituted at the request of the Government by a commission of chemists, namely, Professor Hofmann, Dr. Miller, and Professor Graham, in the month of January 1851. We are therefore in a condition by those comparisons to form some notion of the quality of water at each of those several periods of inquiry, it happening that the inquiries were made in each case in the month of January.

3866. Are those tables made up to the present year?—Yes, all of them. With regard to Table No. 1, that will show the degrees of hardness of the several waters, ranging, as you will perceive, from about 13 to 14½ degrees. It will also show the quantity of gases dissolved in the water, the object of that being to ascertain whether the waters are well aerated or not, which is a very important consideration, in a sanitary point of view. The proportion of gases dissolved in water ranges from about 13 to 14 cubic inches, and the most that water can take up is 15 cubic inches. That shows also that the proportion of oxygen contained in the water is very large, considerably more than is necessary to oxidise the organic matter, but if you look at the last line but two you will find the total quantity of oxygen required to oxidize the organic matter in the water, and in the last line but one there is the quantity of oxygen dissolved in the water, and you will perceive that it is at least five times as much as is necessary for the oxidisation of organic matter. The conclusion from that is that the water is remarkably well ærated; in fact, it is so exceedingly well ærated that we find in its passage along the public pipes or mains the atmospheric oxygen dissolved in it really does effect the oxidisation of organic matter, though the water is shut completely out of the atmosphere, which is a proof of the good aeration of the water. Then the last line of the table represents the quantity of am-

monia in a gallon of water, and that comes to 0·003 of a grain, which is further proof that there is no organic decomposition in the water. (*The witness delivered in the Table, which is the same as Table* 1. *in Appendix A G.*)

3867. Will you now explain the second table?—The second table represents the individual constituents of the water of each of those companies. You will perceive that in round numbers the total quantity of solid matter in a gallon of water ranges from 19¼ grains in the Thames at Hampton to nearly 24 grains which we find in the East London water, and of this proportion the organic matter, as determined by the process called incineration, ranges from about three-tenths of a grain in the East London water to about 1¼ grain in the Lambeth water. But this matter called "loss by incineration" represents other things besides organic matter. The conclusion from it is that the waters are not overcharged with saline matter, for the proportion is no more than is generally found in river waters running from a chalk district. (*The witness delivered in the Table, which is the same as Table* 2. *in Appendix A G.*)

3868. Now, will you explain Table No. 3?—The next Table, No. 3, will probably be more important to this Commission, because it represents the composition of the waters in every month of the year, during the years 1865 and 1866, showing the total proportions of solid matter in a gallon of each of the waters, also the quantity of organic and other volatile matters lost by incineration, and also the quantity of oxygen required to oxidise organic and other matter per gallon. (*The witness delivered in the Table, which is the same as Table No.* 3. *in Appendix A G.*)

3869. You do not start, I believe, with any standard in those tables?—There is no standard with regard to the quality of the water. It is scarcely possible to take any water which can be regarded as a standard; generally speaking, we may say that a water of over 10 degrees of hardness may be regarded as on the side of a hard water, and when below 10 degrees of hardness it may be regarded as on the side of a soft water, and so on in proportion to those degrees.

3870. The Loch Katrine water, I believe, is generally referred to as unexceptionable?—Loch Katrine water is undoubtedly very soft water, but on considering a great number of circumstances connected with Loch Katrine water, as the liability of it to organic contamination, and the tendency of it like all such waters to act upon lead, and the circumstance that it is so frequently tainted with peaty matter, there are very important objections to its use in such a city as London.

3871. (*Chairman.*) Do you think that peaty water is objectionable to health?—No, but it is so objectionable on account of its colour that Londoners would not drink it. I do not mean that the quantity of peaty matter found in the Loch Katrine water would be injurious to health, but I am satisfied, from my own experience and from the reports of Commissions appointed on the continent with regard to the water supply of Paris and Vienna, that the inhabitants of a large capital, using water for domestic and not for manufacturing purposes, would not drink such water.

3872. They would prefer a clear, pure, chalk water?—Unquestionably.

3873. You will find that the last table of this series shows the composition of the pump waters of the City of London, and you will notice how much saline matter is in them, and yet so strong is the public instinct for waters containing saline matters that we could scarcely keep people from drinking those waters during the time of cholera, when such water was considered to be very dangerous, for the pumps were close to the sewers, and when to prevent their being used the handles were taken from the pumps, the outcry was so great that we were obliged to restore them.

3874. That arises from a natural preference in favour of what is called pump or spring water?—It does. The saline matter which is contained in such waters has a tendency to give them an agreeable taste, and moreover they are generally well aerated waters; they are also free from colour, and are cool and grateful to the palate, and on that account there is as it were an instinctive liking for such water.

3875. Do you not think that that arises more from the impression in the public mind that pump waters (I am now speaking of the popular impression) are the best, and persons therefore resort to pump water as that which is the most agreeable for drinking purposes rather than from any special quality of that water as detected in the act of drinking?—No. I should be rather disposed to think, from the public statements which have been made with respect to the dangerous qualities of the pump water of this metropolis, that the public feeling would be that such water is not proper to drink, and that persons are induced to take those waters by their liking for the agreeable qualities of them; and really the preference for those waters depends not on the notion that pump waters are better than others, but on the fact that they are more agreeable to the palate. With the permission of the Commission I will hand in the following table, which shows the composition of the water furnished by the City pumps. (*The witness put in a Table, which is the same as Table No.* 6. *of Appendix A G.*)

3876. (*Mr. Prestwich.*) Do you think that the great bulk of the people who use this pump water in London know the actual origin of the water?—I have frequently reported on the subject, and notices have been put upon the pumps stating, "This is a "dangerous pump, and the water ought not to be "drunk," and indeed the greatest pains have been taken to inform people of the fact that those pump waters ought not to be drunk, but nevertheless they will drink them.

3877. From what I know of the use of these pump waters in the City, it seems that nothing is known about the quality of the waters, that they are sought for because they are so extremely cool and sparkling, and pleasant to drink, and very agreeable to the eye and to the palate also, quite apart from any knowledge of the quality of the water?—Quite so. The quality of the water itself as regards its agreeable appearance, its sparkling character, its cool taste, and so on, is what gives to them a liking for such water, but notwithstanding that we have informed them of the danger of using such water, they will still drink it. Four times have I reported, and my reports have been pretty well circulated, as to the danger of the pumps of the City, and yet the public continue to use them.

3878. Only those persons who went to the pump would be aware of this notice that had been posted up, the greater part of the people who use the water in the City send to the pump for the water, and it is brought by their servants?—There is a great deal of publicity given to the reports of the Commissioners of Sewers in the City of London, partly by reason of the local paper, and partly by the extensive circulation of the reports themselves, that I can hardly think the people are ignorant of the qualities of this water.

3879. (*Chairman.*) Unhappily that the most important and valuable reports are disregarded by the public you have evidence in the City as elsewhere?—Yes.

3879. Having regard to those waters, and the several tests which you have yourself made, what is your opinion generally of the water supplied to this metropolis?—My opinion is founded in the first place upon the actual analyses of the waters over a long period of time, monthly analyses; it is founded in the next place upon an observation of the use of those waters very extensively, and I am bound to admit that there is no evidence whatsoever that those waters are in any way objectionable as a public supply. I am now speaking of the whole of the metropolitan waters.

3880. Notwithstanding the amount of organic im-

Dr. H. Letheby.

29 May 1867.

purity that is your opinion?—The organic impurities are not large in the London waters. The loss by incineration, although a grain, is not regarded as a serious quantity, because the loss by incineration represents a great deal more than the organic impurities. I will now hand in Table No. 4 (*see Appendix A G.*)

3881. Have you any means of contrasting those tests which you have made with the tests made prior to the companies going up to take their supplies at a higher point?—Yes, I have. If you will take the Table No. 4 of this series which I have just handed in you will see the quality of the water in 1851, when they were taking their supplies below Teddington Lock, and also in 1856 when they had just taken their supplies above Teddington Lock, for in 1856 the Honourable Mr. Cowper called for this inquiry to ascertain how the Act of Parliament of 1852, which compelled the companies to go above Teddington Lock, had worked, and then there is also the result of our inquiry in 1867. If you will look at that table you will see improvements in the quality of the waters at each of those periods. In 1851 the total quantity of solid matter in a gallon of water, taking the average of all the Thames Companies, was 21·43, in 1856 it was 21·04, and in 1867 19·48. The next set of facts are the most important with regard to the organic and other volatile matter per gallon. In 1851 the chemical commission reported that the average proportion of organic and other matter per gallon was $2\frac{1}{2}$ grains as nearly as possible. One of those chemists was again engaged in the inquiry in 1856, viz., Professor Hofmann, and he reports the quantity to be 1·31.

3882. It had improved in five years from 2·46 to 1·31?—Yes, and Professor Hofmann in commenting on that fact, and perceiving that it was common to every one of the water companies, says it is a proof beyond all question of the water having improved in that interval, and that it is not an accident, for the experiments were made on both occasions in the same laboratory and by the same people, and therefore there was nothing in those results that could vitiate or in anyway affect the conclusion, viz., that those waters had notably improved between those two periods. I will read his words from his report to the Right Honourable Mr. Cowper. "The total amount of solid "matter in the two years likewise exhibits but unim- "portant fluctuations." Then he puts in italics "*A "very considerable diminution, however, is obtained in "the amount of organic matter.*" In fact in 1856 the waters supplied to the metropolis contained not more than one half of the organic matter which was present in the year 1851. This result is certainly not accidental. The diminution is not merely an average result but uniformly observed throughout. The waters examined in 1851 were taken in January, those investigated in 1856, partly in January and partly in April. The diminution of the organic matter cannot therefore be due to the influence of the season, nor can it be due to any difference in the mode of determining the organic matter in 1851 and 1856. These determinations were made by exactly the same method, for it so happened that the analytical part of the inquiry in 1858 which refers to the organic matter was likewise made in the laboratory in the Royal College of Chemistry. Then he goes on to explain why the organic matter has diminished, and he says that it is by going farther up the river and adopting processes of filtration. If you look at the year 1867 you will observe that the volatile matters amount to 0·98 or less than a grain per gallon. The hardness is reduced also but not much. In 1851 the degree of hardness of Thames water was 14·4, in 1856 it was 13·5, and in 1867 13·3. We have therefore in this table a comparison of the analytical results on the three several occasion when there have been inquiries into the water supplied to the metropolis.

3883. You will observe that the Lambeth Waterworks water contained a larger quantity of organic matter in the year 1867 than in the year 1856?—Yes, in 1856 it was 1·03 and in 1867 it was 1·24.

3884. (*Mr. Harrison.*) The East London water from being 4·12 in 1851 was reduced to 1·14 in 1856 and 0·30 in 1867?—Yes.

3885. (*Mr. Prestwich.*) At what period of the year?—All the samples were taken in January.

3886. Is January about the period of the year when water contains the largest amount of organic impurity?—Yes, it is. You will see in table 3 that the months of the year when we have the largest proportion of saline matter in a gallon, in the case of all the companies, are November, December, January, and February. Those are the wet periods of the year, and during wet weather there is the maximum of solid in the water, whereas in the warm summer months of July, August, and September we have less solid matter in the water than at any other time of the year. At that time the amount is a little under 17 grains in a gallon, and during the wet winter months it is about 21 grains in a gallon.

3887. (*Chairman.*) Then it is evident from those tests that from the year 1851 the water had greatly improved in 1856 and still more so in 1867?—Yes, those investigations show that.

3888. And in your judgment the water now supplied as a whole is unobjectionable?—That is my opinion.

3889. With regard to the condition of the Thames water, you are aware, are you not, that the Conservancy Board under the powers recently granted by Parliament, have power to serve notice upon the several authorities on the Thames up to and including Oxford, to intercept all the sewage and filth which now flows into the Thames?—Yes I am aware of that. I hold in my hand their Act of Parliament.

3890. And they have given a certain number of months to enable those authorities to make that interception, subject of course to an appeal for extension of time if necessary?—Yes.

3891. When that interception takes place, will the water of the Thames in your judgment be greatly improved?—I do not think that it will be much improved. Not but that I am quite ready to admit that the discharge of sewage into such a river is a most improper thing, but considering the powerfully oxydising influence of water upon sewage the many agencies which are at work destroying it, the power of precipitation, the using of it up by vegetables and aquatic plants and by fish, and above all by the power of oxydization, I think that none of the sewage discharged into the Thames can at the present moment be discovered at Hampton, but nevertheless it is very possible that there may be a still further improvement of the Thames water by the adoption of these measures. Certainly there will be an improvement in this manner that if the discharge of the sewage into the Thames were to go on increasing during the next 20 or 30 years, as it has been during the last 20 or 30, we should then probably have such an excess of sewage in the water of the Thames as would render it very unwholesome. But at the present moment I cannot perceive through the most refined chemical processes the existence of a particle of sewage in the water at Hampton where the Thames Companies take their supply.

3892. You have had your attention directed, have you not, to the fact that the river running through the town of Leicester some years ago was greatly polluted from the discharge of sewage, and that the plants and fish were destroyed for three or four miles down the river?—Yes, I know it well.

3893. At the end of the third or fourth mile plants began to revive, fish were seen active, and the water appeared in its normal condition?—Yes.

3894. Have you at all ascertained in what length of time or distance polluted matter will be decomposed and transformed in its chemical qualities; for example, supposing we had the sewage from Richmond poured into the Thames, how far down the river would it be lost as sewage and broken up into other chemical elements?—I have made a very great number of chemical experiments to determine that. I have examined most of the rivers in England, and this is the conclusion

that has been come to not only in my mind but in the minds of all the engineers who have devoted their attention to the subject, that if ordinary sewage containing we will say nearly 100 grains of solid matter per gallon, such as our London sewage, out of which probably something like 14 or 15 grains are organic, be mixed with twenty times its bulk of the ordinary river water and flows a dozen miles or so, there is not a particle of that sewage to be discovered by any chemical processes.

3895. When you use the word flow do you mean at any given rate, or simply the fact of its flowing?—I do not think that the rate affects it so much because if it flows fast and the time is shortened the agitation makes up for the delay of the time. If it is flowing slower, and therefore not likely to be so much agitated and brought into contact with the atmosphere, there is a longer time for the effect, and I do not think a greater rate of flow a matter of very great difference in that respect.

3896. (*Col. Harness.*) If it did not flow at all what would the effect be?—That does not seem to make much difference. If we place water in a laboratory and stand it in an open vessel in which it is not moving at all we find, in the course we will say of something like 24 hours, that oxydization has taken place, and we cannot then discover it. It seems to me that river water contains in itself enough oxygen dissolved to oxydize and dissolve the organic matter of sewage provided you give it a few hours to act.

3897. (*Chairman.*) Is it the fact that sewage discharged into a river to the extent of 5 per cent. of its bulk will at the end of the seventh mile lose its character as sewage and be broken up into other elements which will not be injurious to the public health?—That is the result of my observation and experiments.

3898. (*Mr. Harrison.*) Taking the case of the cholera disease and the discharges from the human body being mixed up with the sewage, do you consider that any germs of that disease would be carried down in the water?—At the present moment we do not know what the germs of the disease are. If the germs of the disease be decomposing matter then I do not think that they would exist in the water; but if the germs of the disease be living matter then it is possible that they may exist in the water, but as nobody as far as I am informed can tell us what the germs of cholera are it would be premature for me or anybody to theorize as to the probability or the possibility of their existing in the water.

3899. (*Chairman.*) That would depend upon the amount of resistance, because we had an account in a French publication recently that a seed after being boiled for four hours vegetated notwithstanding?—I have heard of such cases, but I am very sceptical.

3900. (*Mr. Harrison.*) Have you heard the opinion stated that in the case of the cholera at Southampton the disease had been conveyed by means of the sewage water?—I think it is very likely indeed, my own impression is that the matter discharged from cholera patients is the immediate agent of infection, that if you will take pains to destroy it you will prevent the disease from progressing. Such matters are likely to get into running streams and rivers and they are very likely to get from the drains into the public wells. We have had so many instances of cholera having been traced to such polluted water that I have no doubt that those discharges getting into the water may produce disease, but then comes the question of the extent to which dilution takes place in the rivers, about which I can give no opinion.

3901. (*Chairman.*) You are aware that it has been alleged that the main cause of the cholera in the east of London was due to the water supply, do you entertain that opinion?—No, I entertain the opposite opinion. It was a matter of duty with me to investigate the whole of the circumstances connected with the East London supply. In the first place it was supplied to the hospital to which I am attached, in the next place it was supplied to the eastern division of the city, where, as officer of health, it was my duty to look well into the matter, and in the third place I had a general interest in it scientifically, apart from any official connexion with the subject, and I was very desirous to ascertain whether or not the water had been in any way concerned in the propagation of the disease. I therefore investigated it very fully.

3902. Are there two distinct waters supplied to that district?—Yes, but I will tell you this with regard to it, there is hardly anybody who can say, except in certain parts of the East London Companies district, whether the water had come from the reservoir at Old Ford or whether it had been received from the filter beds at the Lea, which is considered to be a good water, for the water was oscillating backwards and forwards in the mains in such a manner that the engineer himself had no knowledge what water was in any main at any particular time. But on the other hand there are places at which Old Ford water, and that water alone, is supplied, namely, Stamford Hill, Upper Clapton, Walthamstow, Woodford, Wanstead, Leytonstone, North Woolwich, and Silvertown, and excepting the two last-named places there was no cholera in any of them; there was a little in Silvertown towards the end of the epidemic, but the other places were free from it, and those were the only places where we actually knew that that water did go.

3903. Dr. Farr gave evidence before this Commission to the effect that wherever this particular water was supplied, the cholera was most prevalent in that district, and that they could mark it even to the centre of the street, one side of the street being supplied with one water, and the other with another, and that the bad water was marked by the progress of cholera most distinctly throughout the district?—I do not concur in that opinion, and moreover I may say that my brother medical officers of health who have had experience of the cholera in all those districts do not concur in it. I could read an extract from their reports which would show that they do not believe a word of it, and there is no proof of it. It is an assumption to begin with that the water was received from the Old Ford reservoir.

3904. (*Sir B. Phillips.*) Do you think the present supply of water to the London people is wholesome water?—I do, a thoroughly wholesome water.

3905. The chairman has mentioned to you the evidence which Dr. Farr has given in reference to the action of the water upon the cholera patients in the east of London. You have told us that you do not confirm that statement, in other words, that you do not believe it?—I not only do not confirm it, but I know that it is not so.

3906. You do not think that the cholera was induced by the water supplied to the people at the east end of London?—I am sure it was not. I am satisfied from my inquiries that it did not do so, that it had no more to do with the propagation of cholera than the commercial gas had, for there was the like coincidence of the Commercial Gas Company's district being exactly the cholera field, just as the district of the East London water supply was the cholera field.

3907. You visited that particular district, did you not?—Yes, I went into it all. In one division of the City there were 62 deaths in the district supplied by the East London and the New River Companies. Now the New River Company's water is above suspicion, nevertheless, of those 62 deaths in that district, there was only a single house in which the East London water was taken; all the rest were supplied with New River water. At my own hospital, the London Hospital, we had nearly 500 people in the hospital, and they drank nothing but East London water. Those patients may be looked upon as people most susceptible of disease, but we had not a single case of cholera arising in the hospital, though we had such a large number brought in as patients.

3908. (*Chairman.*) You know that the district board alleged that there were two distinct waters supplied to that area. What water was supplied to

Dr. H. Letheby.

29 May 1867.

your hospital?—I have consulted Mr. Greaves, the engineer of the East London Water Company, upon the matter, and he cannot tell you at any time in the day whether it is the Old Ford Reservoir water that is supplied, or whether it is Lea Bridge water, for it is oscillating in the pipes backwards and forwards; but Dr. Farr has taken it for granted that the Old Ford reservoir water was there, but even if it were there, I tell you that it did not produce the disease. I will take another instance, which is a very strong one, I think, in proof of the non-connexion of the water with the cholera epidemic. If this water had been charged, at any particular time, with this cholera poison, supposing, for one moment that that poison were arsenic or alcohol in the water, distributed over the district, there would be some uniformity in the time of the outbreak, or manifestation of its action over the district, but a month elapsed in several of the districts and no outbreak appeared where this suspected water was being supplied. There is no coincidence of time in the outbreak, and there is no coincidence in the intensity of the disease or in its duration along that district. In the next place, people taking that water and drinking it in its unfiltered state did not get the cholera, while the cholera affected people in that district who did not take that water. At one of the city of London workhouses, the City of London Union Workhouse which is in the Bow Road, they did not take a drop of the East London water, but drank the water from their deep well. I receive, and did receive every week, a return of the progress of disease in that workhouse, and they were decimated by the cholera. Another workhouse, namely, the East London Union, has its workhouse at Hackney where they do take that water, there was not a case of disease there; and then at Stamford Hill, and those places where no other water but the Old Ford reservoir water was pumped—for they have a special power to send it to those places—there was no cholera. I say, therefore, it is a very hasty conclusion, because of the coincidence of the outbreak of disease in that locality with a certain water distribution, to say that the water has been the cause of the disease. Mr. Bazalgette wrote at the time to Dr. Farr, to say that that was unfortunately the very locality in which the main drainage operations were not completed, and you will find that according to the level of the district, high or low, so was the intensity of the disease, although the water was taken equally in all those places. I have no prejudices upon that matter, but it was my duty, as officer of health, to investigate this question of water supply, and the conclusion which has forced itself upon my mind as it has upon the mind of every officer of health, except one, is that the water supply has had no connexion with it.

3909. You are not connected, are you, with any water company?—Not at all. I analyze the water, and I supply the results to the medical officers of health, and I supply the results to three or four companies upon the payment merely of the expense incurred by it, but I am not in any way connected with the water companies beyond that.

3910. (*Mr. Harrison.*) In the case of the previous outbreak of cholera, in 1854, was there any distinct connexion between the cholera and the water supplied then?—There was, as it appears from Dr. Snow's investigations, and those investigations were, I admit, to my mind so conclusive, that I had no doubt that the foulness of the water at that time had a good deal to do with the propagation of the disease. But it has been found since that the company's pipes were running in such an intricate manner in the district that the companies themselves did not know which houses they supplied with water. The evidence upon which Dr. Snow founded his conclusions are open to that doubt, that although he got proofs of such and such water companies having supplied the water, yet the whole thing was in such confusion that no one knew what water was given to the houses of any particular district.

3911. Was it not the case that at one time one water company would just open the ground and put a tap into its neighbour's pipe?—Yes.

3912. (*Chairman.*) Apart from the question of the quality of the water, has your attention been directed to the question of the constant, as compared with the intermittent system of supply?—Yes, it has.

3913. What are your views upon that subject?—As an abstract question, there can be no doubt that the constant supply is a very advantageous thing to the public, chiefly because they would get their water cooler, more grateful, less liable to the pollution to which it is now subject after it is delivered by the water companies, and, if the question really turned upon poor people's houses, I should say that the constant supply to them, whether it be in a court by a standpipe, or whether it be in their own yards by a standpipe, would be a boon, the good of which is hardly to be calculated.

3914. You have visited every part of the City, and, as we all know, there are some parts of the City where a very large number of poor are congregated; do you find that the receptacles in which the water is kept are frequently the cause of great mischief to the health of the inhabitants, by standing near to cesspools or privies?—Yes, by standing in the neighbourhood of privies, in dirty cellars, and so on, no doubt it becomes much polluted.

3915. I suppose that the water itself would take up any gas that might be generated in that locality?—It would do so. It does not take it up anything like so fast as soft water. Soft water is very prone to the absorption of gases, almost immediately, but hard water is not, from the circumstance that hard water contains such a large quantity already dissolved in it that it shuts out, as it were, the other foul gases. As I say, in the poor people's houses it would be an incalculable benefit; but with regard to the better class of houses it is a matter open to doubt as to whether or not a constant supply should be granted without a cistern of some kind or other to provide against what must happen more or less frequently in the derangements of the mains, and the shutting off of the water, or something of that sort, and it would necessitate a complete alteration in the present mode in which the fittings of the houses are managed.

3916. (*Sir B. Phillips.*) Were not standcocks supplied in the City during the cholera in different parts of the courts of London?—Yes, in almost all the public courts where it was thought it would be advantageous, and where we did away with the pumps upon which people had been relying for much of the water they drank. The Commissioners of Sewers thought it right and proper that they should supply the poor with water, and they put up standpipes, and both from the East London and the New River Companies we encountered no difficulty whatever; they readily gave us the opportunity of putting up those standpipes.

3917. Have they been withdrawn?—No, they are most of them there; but it is a new thing, and the children play with them to such an extent, and we have had so many memorials from the inhabitants to take them away that we hardly know what to do at the present moment.

3918. (*Chairman.*) During the time that they were in use they were accompanied with a great advantage to the people?—Yes, I think so. There is a table to which I would wish to direct the attention of the Commission, Table No. 5. I have classified in this table the composition of the water supplied to most of the towns in England, giving an account of the appearance of the water when it is examined in a long glass tube; next, the quantity of solid matter contained in a gallon; next the amount of organic matter; then the oxygen required to oxidise the organic matter, then the ammonia, then the hardness, and then the population of each of those towns, and lastly the mortality per 1,000. The object of this is to ascertain whether there is any relation whatever between the mortality of a district and the quality of its water supply, and you will find at the bottom, under the line that where the water

supplied to the towns is over 10 degrees of hardness, which I look upon as on the side of a hardness, the mortality is only 22·2 per 1,000 of the population, whereas in all the towns with soft water, that is with water under 10 degrees of hardness, the mortality is 26 per 1,000, and with the metropolitan water it is 23 per 1,000. I do not pretend to say that the quality of this water has had anything to do with the mortality, but there is this important fact, which comes from the examination of the table, that certainly soft water does not improve the health of the people, and that many of those towns are very comparable. I take Sheffield and Birmingham to be very comparable with regard to the character of the inhabitants, but look at the mortality in the two places. Birmingham has nearly the hardest water that we have in England, and Sheffield has one of the softest waters, nevertheless the mortality of Birmingham is only 24 in the 1,000, whereas you will find that the mortality of Sheffield is 26·2 per 1,000. I do not mean to say that the water has anything to do with it, but it shows that there is no evidence of soft water so benefiting the health of the people as to reduce the death-rate. (*The witness delivered in the Table, which is the same as Table No. 5. in Appendix A G.*)

3919. From your large experience, you would scarcely be prepared to say that the mere question of the supply of good or bad water would actually in itself determine the mortality of a place; there are other circumstances, are there not, which must be taken in account?—Yes, certainly.

3920. For example, take the condition of Glasgow, where they have an unexceptionable water, yet where there is a lack of all other sanitary arrangements, drainage of the town and so on, that might of themselves be a sufficient cause for the increased mortality there?—Yes, and it is one of the largest,—27 per 1,000 is the mortality of Glasgow.

3921. (*Sir B. Phillips.*) The smallest amount of mortality in this table appears to be at Croydon?—Yes; and it is a hard water they have at Croydon.

3922. Was there not a serious outbreak of fever there some time ago?—That was before the water supply. That was at the time when they began the drainage by pipe-drains, and in consequence of the bad ventilation of those drains the gases were all forced into the houses of the people, and a tremendous fever broke out. I have had occasion twice to inquire into the outbreak of fever at Croydon, and I have no doubt it was traceable to that. The pipe drainage system is a system which, unless perfectly carried out and the ventilation is good, is so tight that the gases cannot get out, and they therefore force their way through the valves of the water-closets and get into the houses, and an outbreak of fever ensues.

3923. (*Chairman.*) The best proof of that is, that immediately the alteration took place you found an improvement in the public health?—Yes.

3924. (*Mr. Harrison.*) In Sheffield is not the average of age less in consequence of the knife-grinding that is carried on there?—That may be so.

3925. (*Mr. Prestwich.*) This return appears to be made up to 1861, what was your reason for that?—In every instance the waters which they are taking now were taken in each of those towns in the year 1861, but I am not able to say what the population of those towns at the present time is, nor what the death rate is. I am obliged to take the only reliable information I can get, namely the mortality returns as well as the population in 1861, for they are the only ones that are accessible, but all those towns had the same water in 1861.

3926. Has not the soft water supply to Glasgow been since 1861?—No, it was before 1861.

3927. What do you consider to be a sufficient supply per head of the population?—I think that the experience of engineers generally accords with my own experience of the matter, and I should say that 20 gallons per head for all purposes is a very good and sufficient supply.

3928. (*Chairman.*) Do you mean for all purposes other than manufactures?—No; I mean for all purposes. Taking an average town, taking London for instance, where manufacturing operations are not large, 20 gallons per head is sufficient for London, including everything. I take it that about 16 gallons of that would in all probability be used for domestic purposes, and probably three or four gallons would be used for other purposes; but in towns where the constant system is adopted, and where the management is very well regulated, and the public are prevented from wasting the water, we find upon the average that about 18 gallons is that which is used for all purposes; for instance, that is the case in Nottingham and Norwich. Therefore we may look upon 20 gallons as a very fair quantity. At the present time, I believe, the metropolitan companies are supplying as near as possible 30 gallons.

3929. (*Mr. Harrison.*) In Table No. 4 you take 30·9 as the present supply, do you not?—Yes. The last three columns give the quantity supplied per day by each company in 1851, 1856, and 1867, and then at the bottom of the table you will find that in 1851, the population being so many, the average was 19·4 gallons per head. In 1856 it was 30·2 gallons per head; and in 1867 I may say it is 30·9.

3930. (*Chairman.*) Does your estimate of 20 gallons per head include all necessary supply for street purposes and fires, and every other purpose?—Yes, everything.

3931. (*Mr. Prestwich.*) Apart from the question of organic contamination, about which there can be no doubt, have you any evidence with respect to which is the best water for drinking purposes, soft or hard water?—A moderately hard water is best.

3932. Have you any evidence bearing upon that?—Yes, I have. I have evidence derived from my own inquiries and my own experience, and the evidence of the continental commissions which have been appointed to inquire into the best supply for the large cities of the continent. I will take the case of Paris. The commission appointed a few years ago had opportunities of gathering water from granite districts and from millstone grit districts, I believe, as well as from hard chalk water districts; and upon investigating the facts of the case very carefully the French commission concluded that the evidence went to show that the men were finer grown and that less conscripts were refused upon the ground of insufficient stature or something of that kind in the hard water districts than in the soft water districts; and after much consideration of the subject, they recommended the municipality of Paris to take a water which is almost identically the same as the water of London. Very recently I have received from the government of Vienna the report of a commission appointed to investigate the distribution of water in Vienna, and there again they have abandoned soft water, and have taken to a moderately hard water for two reasons, first, that the evidence goes to show that the men are better formed, that the bones are stronger and better formed, and that there is better health in moderately hard water districts than there is in soft water districts; and, secondly, that the public prejudices against water tainted with peaty matter are so great that a large city should never draw its supply from a soft water district.

3933. (*Chairman.*) Lime is not necessary in water to supply bone, is it?—You cannot say that it is not; probably there is no evidence to show that it is, but there is no evidence certainly to the contrary. Our bones must be made of lime. It is true that milk and the common articles of diet contain generally speaking enough lime to form the young tissues in that respect, but you cannot say how much a hard water or the lime of a moderately hard water contributes to it. And if we are to be guided by what may be termed the Providential evidences with respect to it, $\frac{4}{5}$ths at least of the earth's surface being calcareous districts, that is to say, districts supplying hard water, one would think that if it had been the case that soft

Dr. H. Letheby.

29 May 1867.

water was better than hard, we should have had it more abundantly distributed to us than it is. There are notions abroad that hard waters have a tendency to produce gravel, but I have investigated that subject and there is not an instance of gravel or any surgical affection of the same kind that I can trace to hard water. My own opinion is that water of between 10 and 15 degrees of hardness is in every respect the most proper water for the supply of a city. In the case of large manufacturing towns where the water is used to a very large extent in steam engines and for bleaching and dyeing purposes for which soft water is required, that would affect my conclusions, but in large cities such as London, Paris, Vienna, or Berlin, I have no doubt in my own mind that water of between 10 and 15 degrees of hardness is the proper water, provided that upon being boiled it would be reduced to about 4 degrees of hardness. It is 5 degrees of hardness in any kitchen boiler that you like to take it from in London and that is sufficiently soft for tea, for washing purposes, and for everything that may be required in ordinary domestic use. And in addition to that the water is agreeable, it is almost always colourless, bright, sparkling, and agreeable to the palate, and as far as I know may contribute something towards the nourishment of the tissues.

3934. In expressing those opinions your view would be clearly against the notion of going any distance to obtain a supply of water to the metropolis?—I would not only not go to a great distance, but I would say that if soft water were next door to you, if the Thames itself were soft water like that which is proposed to be supplied to London from the lakes, and there were found in the chalk of the neighbourhood a harder water like that we are now using I should unquestionably advise the harder water to be taken.

3935. Even at additional cost?—Yes, even if the soft were close to you and if the hard water would cost more. I call it hard merely comparatively. I mean water that would range from 10 degrees to about 15 or 16. Beyond that it becomes too hard particularly if it is a sellinitic hardness, if it is sulphate of lime in place of carbonate of lime under such circumstances it becomes objectionable.

3936. (*Mr. Harrison.*) Taking it that the average of hardness of the waters of the Thames companies is only 13·3° that quite comes within your limits?—It does; and I am of opinion from a large experience of the matter, not only from chemically analyzing the water but from observing the effect of it upon the public health, that there is hardly a city in Europe so well supplied with water either as regards quantity or quality as the city of London.

3937. You would not consider it necessary according to your view to apply Dr. Clark's process to this water?—I should not, for I think it would be injurious. If the water were softened by Clark's process, it is not only an expensive process, and as far as I know a very difficult process to carry out on a large scale, for I know of no instance in which more than half a million gallons a day have been softened, but apart from all that the softening process renders the water very liable to attack lead. It did so at Plumpstead to such a degree that they were obliged to replace I believe the whole of the cisterns or nearly so at Plumpstead, at the cost of the Local Board. The carbonate of lime that was in the water was thrown down in the pipes by a process of crystallization afterwards so as to block up the pipes for miles in length. Whenever there is a bend in a pipe it offers a little hindrance to the movement of the water, and the particles as it were strike together, and the carbonate of lime begins to be deposited directly. I have seen pipes become almost entirely shut up with it a long distance from the works.

3938. (*Mr. Prestwich.*) Are you acquainted with the evidence which was given before the board of health, with regard to the economy in the use of soft water some years ago?—Yes.

3939. What opinion have you formed with regard to that?—My opinion is, that it is very much exaggerated, and that exactly coincides with the opinion which the chemical Commissioners, Messrs. Hofmann, Graham, and Miller, formed of it, that whilst one grain of carbonate of lime will actually destroy the detergent properties of 10 grains of soap (and they looked at it from that point of view) it would seem that there is a very large loss of soap, but when you consider that all water before it is used for detergent purposes is heated and reduced to about four degrees of hardness, it very considerably reduces the amount of soap destroyed. Those Commissioners in their report have stated what they consider would be about the quantity of soap destroyed in ordinary washing operations, and in washing flannels and so on, and they have proved beyond all question that the proportion is so small as not to be deserving of consideration. I think therefore that those statements which were made by the old board of health upon that subject, were founded upon wrong premises. They were founded upon the supposition that water was always taken of the degree of hardness that it has in its unboiled condition.

3940. You would separate the permanent from the temporary degrees of hardness?—Yes, the permanent hardness being that upon which I found my calculations, while the non-permanent is that upon which the board of health founded their calculations; and this makes a good deal of difference in the result.

3941. (*Sir B. Phillips.*) Have you seen the scheme of Mr. Bateman?—Yes, I have seen them all. I think there are five or six that have been sent to me.

3942. Supposing that water could be brought from the lakes, and delivered to London at the same cost as the water is now supplied from the Lea and from the Thames, do you think it would be desirable to avail ourselves of such a supply?—I have already said that if we had next door to us instead of at the lakes of Cumberland soft water, and we had the water supplied by our rivers flowing from the chalk districts, I would recommend without hesitation the use of the hard water in preference to the soft water. I have had occasion to examine and analyse very carefully the waters that are flowing from Loch Katrine into Glasgow, and I know the quantity of carbonate of lime that is taken up by those waters in their flow along the channel from the Loch to the city of Glasgow. It amounts to about 500 tons of carbonate of lime are taken up from that channel every year: what will be the end of it in the course of years I do not know. All that carbonate of lime comes, I daresay, from the mortar that joins the stones together, and one would think that it would bring the whole thing to pieces at last.

3943. (*Mr. Harrison.*) It appears that in 1851 the quantity per head was 19·4 gallons of water per day in London. To what do you attribute the large increase which has taken place since that time?—I do not know, except it may be that the companies have perceived the necessity for extending the supply. There has been, as far as I know, no pressure put upon the companies to do it. I do not know that in the course of any inquiries before any parliamentary committees or any Royal Commissions the question of the quantity of water has been raised; therefore I take it that this must have been the voluntary act of the companies.

3944. Has not a great deal of it arisen from the increase in the number of sanitary improvements, waterclosets, the flushing of sewers, and things of that sort?—I daresay that is so. No doubt the use of waterclosets must have created a larger demand for water.

3945. What made you assume that you could go back to that 20 gallons the quantity having risen to 30?—I take the case of towns which are almost entirely provided with waterclosets, such as Nottingham and Norwich. I do not know of any places so well regulated, they are both under local governments, and in both those cases the use of waterclosets is pretty general, and in those places with a constant supply well looked after, the proportion does not ex-

ceed 19 gallons per head, that is the basis of my conclusions upon that point. Then I have founded another conclusion. We have made some very careful inquiries upon the proportions of water used in the better classes of houses as well as in the houses of the poorer classes. In fact it was an inquiry instituted by Mr. Simon and Mr. Haywood, the engineer to the Commissioners of Sewers, and this is the result of their inquiries which helps me in my conclusion upon that point. In first-class houses with from 12 to 20 rooms, with good cisterns and baths, and water supply, and waterclosets, and everything, they take upon the average 12·87 gallons per head. In second class houses, belonging to the better class, but still with good cisternage and waterclosets they take 7·41 gallons per head. Then we come to the poor with their bad receptacles, and they take about three gallons per head. Model lodging-houses come next, where every appliance is used, and where the water is not stinted, and in those cases it is exactly 6½ gallons per head for domestic purposes. Then as to our workhouses, in the Holborn Union, which is more liberally supplied with water than the other workhouses in London, five gallons per head is the quantity, in St. Martin's workhouse, 3·68 gallons per head, and in the Clerkenwell workhouse 3·1 gallons per head. We did upon that recommend that in the city of London 24 gallons should be supplied to every room upon the supposition of four people in a room, which is six gallons per head. Lately I thought it right to advance it to 30 gallons a room. I believe that engineers even in large manufacturing towns consider that scarcely ever does one half of the water go for manufacturing purposes. Therefore taking all those facts together I think that 18 gallons per head seems to indicate a very good supply for all purposes.

Dr. H. Letheby.
29 May 1867.

3946. At the present moment of those 30 gallons the greater part must be wasted?—It is so, there is no doubt about it. I suppose there is hardly a cistern to be found in the metropolis that has not its ball-tap out of order, with waste water running down almost all the time the water is on.

The witness withdrew.

James Muir, Esq., examined.

J. Muir, Esq.

3947. (*Chairman.*) You are engineer I believe to the New River Water Company?—I am.

3948. And have been so for some years?—I have been Engineer-in-chief to the company for more than seven years, and have been connected with them for a much longer period.

3949. You are therefore necessarily acquainted with the arrangements for the conveyance and distribution of the water of that company?—I am.

3950. Have you added at all to your capacity to supply of late years?—We have, and are still adding.

3951. Will you state what are your sources of supply, and how you have added to them, and what you propose to do in increasing that supply?—The sources of supply were originally the Chadwell and the Amwell springs. These were brought to London 250 years ago by Sir Hugh Myddelton. They were soon found not adequate, and a supplemental supply was obtained from the river Lea at a point between Hertford and Ware. The exact date of that I cannot tell, but it is supposed to have been not very long after the original bringing of the water to London by the New River. The point at which the company then drew water was between Hertford and Ware, and at that point they still draw, having diverted from it all the sewage of Hertford.

3952. Can you state the quantity which you draw from the springs, and the quantity which you are taking from the Lea at that point?—I should state that the Amwell spring, (one of those originally brought by Sir Hugh Myddelton) some long time ago passed into the river Lea and ceased to flow into the New River, and that now we have flow only from the Chadwell spring and the supplemental supply from the Lea.

3953. How far are those two springs separate?—They are only about two miles apart.

3954. Has the quantity of water in the basin of the Lea been enlarged so as to lead you to suppose that that spring has been tapped?—I do not know how originally the Amwell spring poured itself into the New River channel. It is close to the New River channel now, and the water of that spring finds its way at a lower level than the New River channel into the Lea, and we make no use of it.

3955. Can you account for that?—No.

3956. That must necessarily arise from depression of the water, has it been from any fresh tax upon the water?—Not at all. It may have been that the Amwell spring broke for itself an outlet at a lower level and so reached the Lea, instead of entering the channel of the New River.

3957. Can you state the quantity that you are now taking from the Chadwell spring?—We reckon that the Chadwell spring has an average flow of 400 cubic feet per minute or 3,600,000 gallons per day. That is the daily average. Sometimes the flow is very much more.

3958. Is that the average for a year?—It is the daily quantity for an average of years because the average of last year was 500 cubic feet per minute or 4,500,000 gallons per day. I may state that by Act of Parliament we are entitled to take in priority 2,500 cubic feet per minute from the Lea, that is 22,500,000 gallons per day.

3959. That I understand is your statutory limit, which are you actually taking?—The whole of our supply during the past year, was on the average 22,898,769 gallons a day from all sources.

3960. I understand that your maximum supply from the Lea, that which you are entitled to take under that Act, is 22,500,000 gallons?—We are entitled to take that *in priority*, but I should explain that that same Act of Parliament, to which I have alluded, empowers the New River Company and the East London Company together to obtain an additional quantity, in fact all the water of the Lea except a certain navigation quantity.

3961. You have a first claim upon the river to the extent of 22,500,000 gallons; I want to know whether you are taking up to your maximum quantity your legal quantity?—We took last year from the Lea about 18,000,000 gallons per day, on the average.

3962. (*Sir B. Phillips.*) What other sources of supply have you?—I will mention the other sources. We have six deep wells in the chalk; we have also, by purchase from the Hampstead Waterworks Company, the springs at Highgate and Hampstead collected in ponds there, and used for street watering, by separate mains; we have also power to draw water between Blackfriars Bridge and Southwark Bridge from the Thames. This is a power which the company have not exercised for many years, but they have there the means of taking water; they have a large suction into the Thames, and at any time when required they could draw water there for sewer purposes and street purposes, distributing such water by separate mains, so that it should not mingle at all with the supply for domestic purposes.

3963. (*Chairman.*) Have you duplicate mains throughout your district?—In some parts of the district we have separate mains, but for the general distribution of that Thames water for street and sewer purposes new lines of mains would require to be laid down, and the company contemplate laying them when the necessity for so doing shall arise.

3964. (*Col. Harness.*) Have you separate mains for the Hampstead and Highgate water?—We have separate mains for that water.

3965. (*Chairman.*) You stated, did you not, that

J. Muir, Esq.
29 May 1867.

the whole quantity which you distributed during the past year was 22,898,769 gallons per day?—Yes.

3966. (*Sir B. Phillips.*) Of which you took, I think you said, 18,000,000 from the Lea?—Yes.

3967. Where did you get the balance from?—We obtained 4,500,000 gallons from the Chadwell spring, and the rest from those ponds which I have mentioned at Highgate and Hampstead.

3968. (*Mr. Prestwich.*) You also stated, did you not, that you got some from wells?—Last year we hardly worked the wells, they were not required; we had them as a stand-by.

3969. What is the maximum quantity that you have obtained at any period from those wells?—We are remarkably fortunate in our ground for sinking wells. At Amwell Hill the yield is about 2,400,000 gallons a day from one well, and at Amwell End, not very far distant, a second well will yield about 2,500,000 gallons a day.

3970. Have you any other source to be added to your present means of supply?—We have that to which I alluded, namely, the power of obtaining, *pari passu* with the East London Company, any quantity of water that may be found in the valley of the Lea beyond the 22,500,000, a certain amount only being reserved for navigation purposes.

3971. Are we to understand that you are tied up to 22,500,000?—No, I stated that we had the power to take that quantity *in priority*, and then any further quantity *pari passu* with the East London Company, a certain amount being reserved for navigation purposes, all this being arranged under the River Lea Act, 1855.

3972. What is the plus of 22,500,000 gallons divisible between yourselves and the East London Company?—That additional quantity could only be obtained by making store reservoirs in the valley of the Lea. We contemplate making such reservoirs when we are so near our present limit as to make it necessary: and from the river Lea I calculate that we could get by making those reservoirs an additional supply probably of 10,000,000 gallons per day for the New River Company.

3973. Where do you propose to store it?—The best point for the collection and storage of the surplus water of the Lea I think would be below Field's Weir.

3974. Where is that?—It is near Hoddesdon.

3975. How far from London?—About 15 miles.

3976. What would be the gathering ground there?—There are several sites which would be available for reservoirs on the left bank of the Lea at that point. Higher up, the water might also be gathered into reservoirs, but there the difficulty of a non-retentive soil would make it a very expensive thing to construct reservoirs, as the clay, which is so useful in making a reservoir, does not appear until you come down the valley to Hoddesdon.

3977. You do not intercept any tributary, but you fill your reservoirs, do you not, out of the Lea itself?—Yes, out of the main stream.

3978. Then it would be simply a matter of choice as to where you should place your storing reservoir?—Yes.

3979. (*Sir B. Phillips.*) What amount of water are you allowed under your Act to draw from the river Thames between Blackfriars and Southwark Bridges?—There is no limit. We have not used that source for many years, but it is one which may be used for street and sewer purposes to any extent.

3980. You say that in addition to the 22,500,000 gallons which you now draw from the river Lea you might by making reservoirs draw another 10,000,000?—Yes, speaking roughly. The necessity for calculating the thing in detail has not yet arisen, but I think, looking at the gaugings of the river Lea, which have been very carefully taken at Field's Weir, there would be by proper reservoirs that quantity to be had in addition to the quantity which we now have.

3981. Then I understand you to say that you have two wells at Amwell Hill from which you draw something like 5,000,000 gallons a day?—Yes, we have; and we have a well at Cheshunt, and we have a well also in London at the Hampstead Road, and we have one on Hampstead Heath. The two last-named have not been used for many years, simply because there has been no occasion for it.

3982. (*Chairman.*) Have you observed a depression in the water of that well?—I have observed a depression in the wells in town, but not in those of Hertfordshire.

3983. To what extent?—The depression probably during the last 20 years in the Hampstead Road well may be very nearly 20 feet, arising, I should suppose, from the greater number of wells now in London, and the greater draught therefore from the chalk reservoir below; but the depression has not been apparent at all in Hertfordshire. The level stands as high in the Hertfordshire wells as it did 12 or 13 years ago.

3984. (*Mr. Prestwich.*) Including the one at Cheshunt?—The one at Cheshunt I cannot speak so accurately about. I happen to have a note of gauging by my predecessor, Mr. Mylne, at Amwell Hill, and therefore I speak of it certainly as not having fallen off. I think there may be a slight falling off in the Cheshunt well as you come down the valley, and then in town there is the greater falling off that I spoke of.

3985. (*Chairman.*) You bring the water by an open cutting the whole way, do you not?—It is covered for a distance of perhaps two or three miles.

3986. From where?—Part of it is tunnelled at Wood Green, near London, and part of it (after the river enters London) is enclosed by a brick arch and by pipes.

3987. What is the sectional area of your culvert? It is an open channel for the greatest part of the way.

3988. What is the size where it is covered for three miles?—The diameter of the tunnel, I think, is something like 14 feet.

3989. The rest of the cutting is open cutting?—Yes.

3990. Have you experienced any inconvenience from the frost or snow in the winter?—It requires labour in severe frost to keep the river clear by breaking the ice at the edges.

3991. I suppose it is necessary to release the ice from its hold at the side in order that a proper quantity may be supplied?—It is.

3992. But have you found any difficulty beyond the amount of labour necessary for breaking the ice on either side?—Many years ago I have heard that in very severe frost the river through frozen ice and snow was choked, so that for some time the supply was interrupted.

3993. For how long do you remember?—I do not remember, it was before my experience.

3994. Have you during the time that you have been engineer to the company observed any inconvenience arising to the water supply from a fall of snow?—There has been no interruption of the supply at all, but it has required a considerable amount of labour to break the ice at the edges as I have described, and to pull out at the gratings in the course of the river the lumps of ice which float down; men are kept night and day pulling the ice out to prevent its accumulation.

3995. Does not that entail considerable cost on the company?—In severe frost it does.

3996. Can you state what has been the cost of that operation?—I cannot exactly.

3997. How many men for example are necessary?—According to the severity of the weather the men are taken on, and I should think that a severe frost would cost us something like 500*l.* or 700*l.* for labour only.

3998. After the ice has been broken have you experienced no other inconvenience?—We have not.

3999. (*Sir B. Phillips.*) Supposing it were necessary to increase the supply to London, have you considered what quantity of water you could deliver from your present available sources?—The whole

quantity which we have the power of delivering now is more than 35,000,000 gallons per day.

4000. How much could you increase that from sources that you know of?—I hope by a new well now being sunk in the chalk at Wormley to obtain 2,500,000 gallons extra. By mains driven from the Thames in the way already described, I could find the means of disposing of another 2,500,000, and by making reservoirs in the Lea I could store a daily quantity of 10,000,000 gallons, and I think you will find the total to be 50,000,000 gallons a day.

4001. (*Mr. Harrison.*) Practically you could fully double your present quantity?—Yes, that would be more than double the average supply of last year which was under 23,000,000 gallons.

4002. (*Mr. Prestwich.*) What distance apart are those two wells in the neighbourhood of Ware from which you draw supplies?—They are not more than a mile apart.

4003. Have you pumped them both at the same time?—They have been pumped both at the same time without any effect being produced by the one upon the other.

4004. And did the pumping produce any effect upon the springs?—None whatever.

4005. (*Mr. Harrison.*) You have I suppose your reservoir in the chalk behind you?—Yes, we bore into the chalk at once, and the hills rise immediately at the back of the wells and supply them directly.

4006. Have you any driftways into the chalk at the bottom of your wells?—Not in all those wells; in the wells at Amwell Hill and the Hampstead Road which I mentioned we have.

4007. (*Mr. Prestwich.*) What is the depth of those two wells?—The depth of the well and bore together at Amwell End is about 390 feet, the Amwell Hill well 160 feet, the Cheshunt well 172 feet, the Hampstead Heath well 458 feet, and the Hampstead Road, well 237 feet.

4008. Have you tried the effect of sinking anywhere else besides those two points near Ware; for instance, have you tried nearer to Hertford?—By boring I have in several places.

4009. What has been the results of those trials?—Water was obtained in each case with great facility. I find that I have omitted to name, among the company's six existing wells, a new well at Hoddesdon in Hertfordshire.

4010. (*Sir B. Phillips.*) In these 50,000,000 gallons per diem, do you take into consideration any quantity that you might draw from the Thames?—Yes, I have put 2,500,000 for that, as I could find customers for it to that extent; but if the demand for such water increased we have the means always of meeting it from the Thames to a much greater extent than 2,500,000 gallons per day.

4011. Irrespective of that you are merely speaking I apprehend of the quantity which your consumers would like of you?—Yes.

4012. (*Mr. Harrison.*) The Thames water I presume would be merely applicable for street purposes?—Merely for street purposes, and similar uses. Therefore although we could take water to an unlimited extent from the Thames, I have only put down an amount that I can now find a use for.

4013. (*Chairman.*) I understand that you merely hold the Thames as an auxiliary aid in the event of a great pressure upon your ordinary supply for street purposes, the Thames water would answer your purpose?—Exactly so—for the streets, for fires, and for the sewers.

4014. (*Sir B. Phillips.*) What amount of capital have you in your company?—The company's capital now is 3,019,958*l.*, that is the amount which they have power to raise. The amount expended at the end of last year was 2,528,667*l.* 17*s.* 9*d.*

4015. (*Chairman.*) Is that the paid up capital or the nominal capital?—The capital of the company was settled in this way. During the inquiry of 1852 it was fixed by Parliament on a valuation of the company's works at 1,519,958*l.* Subsequently the company obtained powers by Acts in the years 1852, 1854, and 1857 to raise an additional 1,000,000*l.*, and last year they obtained power to raise 500,000*l.* more.

4016. That was for structural works, I presume?—Yes, for works.

4017. (*Sir B. Phillips.*) Is that capital raised by additional shares or by debentures?—The 1,000,000*l.* authorised under the Acts of 1852, 1854, and 1857 is borrowed money, the rest is in shares.

4018. (*Mr. Harrison.*) Would the present conduit be of sufficient capacity to carry that additional quantity of water to London which you calculate upon?—If not now of that capacity it can be made of that capacity with great ease. It varies in its sectional area. It was calculated, at the time when the company obtained power to improve their works in 1852, that the then proposed improvements would make it capable of carrying 50,000,000 gallons, and those improvements I believe were fully carried out, therefore I may say that even now the river is capable of carrying nearly double what it carries at present. The fall is such that by the slightest enlargement at those places where we have drops in the river that quantity could be easily brought on.

4019. Would the East London Company also be able to obtain a larger quantity for the supply of London from reservoirs in the upper sources of the Lea?—The reservoirs in the upper sources of the Lea would not yield water enough for both companies.

4020. Therefore if you were to take this additional quantity which you have mentioned, you would be taking all the surplus water of the Lea?—No, the 10,000,000 gallons I now calculate on is only about half the surplus.

4021. Would the East London Company be able to take that additional amount?—If they also made store reservoirs at about the same place below Field's Weir, which I have indicated for our use, they might obtain 10,000,000 gallons also.

4022. Have you tested the degree of hardness of the waters which come from the chalk wells?—Yes, we have had analyses made. When first brought up, the well water is somewhat harder than the water of the Lea, but it rapidly softens by exposure, and after mixture with the river water in our channel, the hardness of the two together is less than the hardness of the Thames.

4023. Taking the water where you take it from the Lea, and taking it at the point of delivery at the lowest end of your conduit into your reservoir, have you analysed the waters taken from those two points of your system?—We have had it regularly analysed as delivered at our works in town. Two analyses are made every month; one of the water as delivered to the works, and one as delivered to the consumers from the mains.

4024. But I want to see what change takes place in the passage of your water over the 16 miles of open conduit through which it passes?—I have had such analyses made, but only a few, and they show comparatively little change except in a slight softening of the water and in a less amount of organic impurity at the London end than at the other end.

4025. (*Chairman.*) Is there any chalk deposited in your water?—None whatever.

4026. (*Mr. Harrison.*) Has your attention been at all directed to the question of the softening of water?—It has. The suggestion having been repeatedly made that chalk water, if softened, would be almost superior to any other waters, the only thing that has prevented the company from doing that is the difficulty of accomplishing it on a very large scale, and also the risk that we have apprehended of a deposit by the crystallization of lime in the pipes, and the pipes being thereby choked.

4027. You in that respect confirm Dr. Letheby's evidence that where Dr. Clark's process has been used there has been an immense deposit of lime in the pipes?—That has been said, but I have no experience of it myself, not having tried it.

4028. Have you formed an opinion in your own

J. Muir, Esq.

29 May 1867.

mind, assuming it to be a practical thing to do it economically, as to the necessity of softening the water by any such process?—I think, taking into account the fact that the temporary hardness of the New River water is so much greater than its permanent hardness, that the gain would not be very great; and from the difficulty of applying the process on a large scale, and to the large quantity of water used for sewer flushing and street watering, and other purposes, (where the softening process is really useless,) we have not much encouragement to go into the thing.

4029. You have not any doubt at all that by the system of reservoirs, and the other means of supply at your command, you could increase your daily quantity so as to make it 50,000,000 gallons a day, if there was a necessity for that quantity?—I think it might be so, and there are yet means, I believe, of adding to the company's supply by sinking wells; and not only so—when the limit to be obtained from well sinking has been reached, the New River Company would be quite ready to co-operate in developing more fully the great capacity of the London basin, of which the Lea is but a part, for a great deal is yet to be done in the way of obtaining water from the Thames valley.

4030. Your attention, of course, connected as you are with the water supply in London, has been directed to the Thames valley as separate from the Lea?—It has.

4031. Have you gone into that to such an extent as to justify you in giving this Commission an opinion as to the capacity of the Thames valley?—Only in this general way; knowing the area of the Thames basin, and the very small amount of the rainfall of that basin, which is now used for the supply of London, it is quite clear that there is an immense quantity of water in it yet for use.

4032. You have made observations, have you not, on the rainfall and evaporation on the Lea?—Yes.

4033. Will you give the Commission the result of those observations?—I believe the average rainfall of the Lea valley may be stated to be 25 inches per annum.

4034. How much of that would be available?—For the formation of streams in the valley—between five and six inches are available.

4035. (*Chairman.*) Is that the average over a series of years?—Yes. I have gaugings as far back as 1850.

4036. And that average is 25 inches?—It is rather more than 25 inches.

4037. And you are of opinion, that after making a deduction for evaporation and absorption, and every other source of abstraction, about five inches of that 25 finds its way into the river, or, in other words, is really available as a water supply?—It is so, and the fact is ascertained by the actual gaugings of the stream.

4038. It is the net result, in point of fact?—Yes, it is the net result. The absorbing character of the soil on which that rain falls, it being chalk, has the effect of taking so much into the great reservoir below that there is only five or six inches left for the formation of streams.

4039. Is that partly due to the absorbing power of the soil, and partly due to the Thames basin being taxed by artesian wells, depressing the water from time to time, and thus giving it greater power to absorb?—I think it will depend more upon the character of the surface on which the rain falls; the surface on which the rain falls in the upper part of the Lea is very largely a spongy and chalky surface.

4040. Supposing that the Thames basin itself is tapped now by those wells, at different points, it is perfectly clear that up to that point the absorbing power is mastered?—Yes.

4041. Is not the fact of that basin being lowered, and the water depressed in it, the cause of a large amount of abstraction of water which falls upon the surface?—I think if the chalk formation is more abundantly penetrated by wells, the effect would be to draw down the water lower in the chalk, so that the chalk would become more recipient of rain. It would take in more rain, and to that extent there might be effect on the quantity of water coming down the stream.

4042. That is to say, if the present tapping were stopped, and the water, instead of being depressed, were to rise up to the surface and discharge at several outlets, the absorbing power of that area would be lessened to that extent?—Less water would, probably, go down into the chalk, and more would flow off in floods.

4043. (*Mr. Harrison.*) What was the date at which the Amwell spring ceased to yield water?—I do not know; it was a very long while ago.

4044. Was it before any influence could have been brought to bear by the act of pumping from your wells?—Yes, many years before.

4045. Has the question of running driftways for some miles into the chalk, and bringing the water out by gravitation, ever presented itself to you?—If you mean running a driftway into the side of a hill where the hills rise to a great height above us, it has not. The means of sinking vertical shafts into the chalk have been so easy, and we have got by that process so abundant a supply, that none seemed better.

4046. You are obliged, are you not, to pump those wells?—Yes, we are.

4047. (*Chairman.*) Do you know whether the system of running driftways has been tried in any part of the basin, and what has been the result?—I do not.

4048. (*Mr. Prestwich.*) I think you stated that although it is possible that the well at Cheshunt might be affected by the pumping in London, yet still the wells in that valley are unaffected by any such cause?—They appear to be quite unaffected.

4049. (*Mr. Harrison.*) Do you find the level of the water in those wells vary much after continued dry seasons?—It does slightly vary with the seasons, a wet or a dry year will make a difference, but no very great difference, only a few inches.

4050. (*Mr. Prestwich.*) Within what distance from the surface does the water rise?—In the higher wells of Amwell End and Hoddesdon it comes within a few feet of the surface.

4051. Have you been pumping at the Hoddesdon well?—Only experimentally, we have had no occasion to use it as yet. We do not know what quantity we shall get, inasmuch as the bore at the bottom of the well is now being carried down, but we have from the experimental bore a considerable supply exceeding 2,000,000 gallons.

4052. Do all those wells draw the water from the chalk?—All directly from the chalk.

4053. Can you put in an analysis of any of the waters from those wells?—Yes, I will do so.

4054. (*Chairman.*) Has your attention being directed to the question of constant supply?—It has.

4055. Do you see any practical difficulties in the way?—In London there are no doubt great difficulties. In a town to be supplied for the first time I think everyone would admit the desirability of a constant supply, care being taken to have everything in reference to the fittings of the houses of a proper description, and means being taken to have such supervision as would keep everything in order. The difficulty in London will arise from the amount of change required to make *old* premises ready to receive the constant supply. The position of the New River Company has always been this, that if their consumers will only take the supply without waste there would be no objection to give it on the constant system, and the advantages of the constant system would be very great in the houses of the poor. I think that the one disadvantage of the intermittent system is its needing cisterns that are liable to become fouled: and in the houses of the poor it is a most difficult matter to have cisternage so placed as not to acquire some foulness by vitiated air or other contamination. The New River Company have repeatedly offered to furnish the houses of the poor with a constant supply if the landlords of such

property would only take water in some way that would insure the company against waste.

4056. (*Sir B. Phillips.*) Has application been made by some of your consumers to your company to supply them on Sundays?—Yes, and that application has in very many cases been granted.

4057. (*Mr. Harrison.*) What is the level of your reservoirs where you filter above ordnance datum?—They are about 86 feet above the Thames high water.

4058. Has your attention been directed to the consumption per head, and what you would consider, taking all things into account, to be the proper consumption?—It has, and I have made experiments upon a pretty extensive scale, for the purpose of ascertaining what would be a fair amount for various purposes in London. In houses of an average class, where means were taken to prevent waste, but where there was no stint (where there was a full allowance of water), the consumption has not exceeded seven gallons per head per day. In houses of a larger class the consumption is somewhat greater and in small houses somewhat less. But I have been in the habit of allowing 10 gallons per head per day as ample for ordinary domestic purposes.

4059. Including all other requirements, what do you put it at?—I have said that 20 gallons per day in a city like London, where manufactures are by no means many, would be a very good allowance.

4060. (*Chairman.*) Would that include manufacturing purposes, street purposes, the suppression of fires, and every other purpose?—For manufacturing purposes to the small extent found in London, for all fire purposes, and for all street and sewer purposes, as well as for every domestic use, 20 gallons per head per day would be sufficient.

4061. (*Sir B. Phillips.*) That is over the metropolitan area?—Yes.

4062. (*Chairman.*) That would be 60,000,000 gallons a day?—Yes.

4063. (*Mr. Harrison.*) Taking the present consumption to be 30 gallons per head per day, to what would you attribute the difference?—The difference is due entirely to waste.

4064. Do you think that means can be taken to prevent that waste?—I think a great deal more might be done than is done now for the prevention of waste. The companies, and the New River Company I may say especially, have attempted to check waste to some extent for the sake of the consumers, (for the waste of one set of consumers is very injurious to another, who may be upon a higher level,) and they have succeeded in some measure in reducing waste, without in the least degree stinting the proper supply of their tenants.

4065. But taking it as a practical question, do you believe that the present supply being 30 gallons, you can calculate that it could be reduced to 20 gallons?—I think it might. Were a constant supply introduced it would be necessary to have very strict supervision indeed, for the purpose of preventing waste, and if that strict supervision could be borne by the inhabitants and if the requisite power were granted to the companies or to local authorities to control the condition of things in houses, I think that the supply might be brought within more reasonable limits than it reaches to now.

4066. You have been examined upon that point before Mr. Ayrton's committee, have you not?—I have.

4067. Do you advocate the entire abolition of cisterns in the case of a constant supply?—Not at all, I think it would be a very inadvisable thing. I believe the whole question was gone into in the years 1851 and 1852 before Parliament, and the result come to then was that cisterns should in all cases be provided, and it is so arranged in the Metropolis Water Act of 1852. I think in all houses of a better description where there is a possibility of putting cisterns in proper places, cisterns should still be required and only in the houses of the very poor should cisterns be dispensed with, and water taken on the constant system through some waste preventing apparatus.

4068. (*Chairman.*) Although you would retain the cisterns, you would still have a constant pressure upon your mains?—There would still be a constant pressure upon the mains, and a constant pressure upon all mains would be decidedly an advantage, especially for fire purposes. When I speak of mains under a constant system I mean all the companies' pipes, because at present a portion only of the companies' pipes are always charged, and they alone are called "mains" by the companies. Other portions (the branch pipes of the companies) are intermittently charged and they are called "services." The effect of giving a constant supply to all those pipes would be to enable a direct fire supply by a hydrant to be taken from the "services" as well as from the "mains." But I still say that the difficulty arising out of the enormous expense which would be thrown upon the owners of house property in making houses fit to receive a constant supply would be so great in London, that a general adoption of the constant system here appears to be almost impracticable.

4069. (*Mr. Harrison.*) Of what could that expense chiefly consist?—It would chiefly consist in laying down new lead pipes for those at present in use. Many of the lead pipes in London are very old and very feeble, and the least increase of pressure would cause them to give way. The fittings also are of a very imperfect kind. Under the intermittent system those pipes are all saved from the night pressure. The pressure of water at night when no one is drawing from the mains, is very much greater than the pressure during the day, and as houses are now served, those lead pipes are only subjected to pressure during the day and are saved therefore from the higher pressure of the night. Under the constant system they would come under that higher pressure, and in the great majority of cases they would give way.

4070. If your view is correct that you could reduce the consumption per head from 30 gallons to 20, there would be a saving in that case of water to the water companies of 33 per cent.?—There would.

3071. Would not that saving of 33 per cent in the quantity of water that they supply, enable the water companies to bear such an expense as would be involved in the alteration of the services to the houses?—I think not.

4072. (*Mr. Prestwich.*) Would the system of constant supply entail a large expense upon the water companies?—To a certain extent. The New River Company has already incurred a very large expenditure in preparations for the constant supply. It was arranged by the Metropolis Water Act of 1852 that the companies should prepare themselves after an interval to give a constant supply, and that if four-fifths of the inhabitants on any district main should come to a company asking for a constant supply, and put themselves in order to receive it, the company should be bound to give it. Under those Acts of 1852, 1854, and 1857, which I mentioned, the New River Company laid out something like 800,000*l.* in the general improvement of their supply, providing filtering beds, laying down large new leading mains, and constructing high service covered reservoirs, all of which were in preparation for this improved constant supply. As yet no applications have been made for a constant supply, and a constant supply therefore has not as a general rule been given, though there are exceptional cases in the New River district where the supply is constantly on.

4073. (*Col. Harness.*) What do you understand by the householder putting himself in a position to receive the constant supply?—The lead pipes must be made of sufficient strength by him, that is, for his own sake. He must take the water for the watercloset use out of a service cistern with a double valve, so that there shall not be waste in the watercloset (one valve always being shut while the other is open). While the water is being drawn into the closet the water is prevented from coming from the main into the cistern, and so waste is effectually prevented. He would require to have all his ballcocks and taps of the best description, and one thing which has been found almost always necessary in every house in which a constant supply

J. Muir, Esq.

29 May 1867.

has been given is to forbid overflow or waste-pipes from cisterns, so that consumers shall have a very good reason for taking care that ball-cocks are always in perfect working order.

4074. (*Mr. Harrison.*) What do you calculate the average to be per house for making those necessary alterations?—I have calculated that on the average, to do the thing properly, it would take something like 8*l.* per house all over London in order to put the houses in a proper condition for receiving the constant supply.

4075. (*Col. Harness.*) That 8*l.* would lie between two extremes; what would it be for a small house, and what for a large one?—I think for a small house it might take 4*l.* or 5*l.*, and in larger houses a very great deal more.

4076. Would you say 12*l.* or 14*l.*?—Yes. Where the pipes are built into the walls and have to be cut out and the decorations made good, the expense might be 20*l.* and upwards. In some cases it has been said and often felt, I believe, that the companies obstinately stand in the way of a constant supply. I do not think that at all to be the fact. If a constant supply could only be carried out here in London as it is said to have been carried out in some other places, with a great reduction in the quantity of water consumed, the companies should hail it; it would be a great matter to them to be able to dispense with the services of many turncocks, and save water at the same time.

4077. Is your annual expenditure large in proportion to the quantity of water delivered?—The pumping and filtering expenses are considerable, but they are small, compared with the general expenses.

Analysis of Water from Deep Chalk Well, Amwell, Herts.

	Grains per Gallon.
Carbonate of lime and magnesia	15·51
Sulphate of lime	2·51
Alkaline chloride	1·12
Alkaline nitrate	0·24
Silica and alumina	0·67
Organic matter	0·52
Volatile matters and loss	0·98
Total	21·55

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 30th May 1867.

Present:

Sir John Thwaites in the Chair.

Sir Benjamin Phillips.	Thomas Elliot Harrison, Esq.
Colonel Harness.	Joseph Prestwich, Esq.

H. H. Fulton, Esq.

30 May 1867.

Hamilton Henry Fulton, Esq., further examined.

4078. (*Chairman.*) I think in your evidence on the former occasion you had arrived at the point when you were about to describe the estimate for your plan?—Perhaps before entering upon that you would allow me to state that I have the returns here of the rainfall to which I referred, and which were taken at Cefnfaes, near Rhayader, and a copy kindly furnished me by the observer. I had not the returns with me on my last examination, but now I have them up to the end of the year 1866. From 1858 to 1866. As I stated, the position of this rain gauge is nearly the lowest point in the watershed No. 1, to which I referred, and consequently I consider that the results are very much lower than would be obtained in the higher portions of the watershed. For those nine years I find that the average is 45·13 inches.

4079. Have you any other gauging?—This is the only gauging that I have in that district. There are others in the neighbouring valleys but not in the immediate district.

4080. Can you tell the Commission the smallest amount of rainfall which occurred between 1858 and 1866?—The smallest that has been observed was in 1858, which I believe generally throughout the country was a very dry year; in that year the amount was 35·11 inches.

4081. What is the highest year?—The highest year is 1860, which gives 59·52 inches.

4082. Have you any other information to give us with respect to the rainfall?—There is one point which I should be very glad to draw particular attention to, which is this, that I have taken the net available amount of rainfall in this district at 30 inches, which I stated before, but which I wish to draw particular attention to because I understand that Mr. Bateman in his Severn plan takes it at 36 inches.

4083. Do you think that the rainfall in your district would be equal to that in Mr. Bateman's district?—Yes. I cannot conceive that there should be any difference.

4084. You are just on the other side of the ridge, are you not?—Yes, just on the other side of the ridge.

4085. How do you arrive at the 30 inches net rainfall which you say would be available for the water supply?—It is on the assumption that the minimum rainfall of the district averages 60 inches, but then in order to give a considerable margin of safety, from that I deduct 30 inches.

4086. But the only evidence you have is this gauge which has been accurately kept you say from 1858 to 1866, and that gives an average of 45 inches, and that gauge was kept at the lowest point?—Yes; and therefore I assume that in the higher portions the rainfall must be very much larger than it is at this particular point, and also as the circumstances of the locality are very similar to the lake district, I consider I am safe in assuming that the rainfall is something similar to the rainfall of the lake district, and I think that the observations which I have just been referring to tend to show that that is so.

4087. Assuming that it would be equal to that of the lake district or that the 45 inches is a fair test of the yielding power of that area, how do you ascertain the abstraction by evaporation and absorption; what means have you of determining that?—It is only from observations which have been made in other instances. For instance, Mr. Bateman, who has had as much experience in that kind of thing as anybody, puts it, I think, from 9 to 16 inches.

4088. That is dependent, is it not, upon the nature of the surface, whether it is of an absorbing character or not?—Yes; but the surface of the whole of this district is of the Silurian formation, and is composed entirely of clay and rock, and the consequence is, I consider, that there must be a less amount of absorption in this district than there would be in almost any other.

4089. From its mountainous character you think that the water would rapidly run off?—Yes, I think so, because the hill sides are very steep as well as the material being very non-absorbent.

4090. (*Mr. Prestwich.*) I suppose there are very

few springs in the district?—I do not think there are very many springs in the district. By far the principal portion of the water would be derived from the rainfall and not from the springs.

4091. Therefore, beyond your rainfall you would have nothing to fall back upon?—There are springs; when I say there are no springs, I mean that comparatively speaking, compared with the total quantity of water derived from the rainfall, the quantity derived from springs would be small.

4092. The rocks being hard and non-absorbent they would not store water?—That does not quite follow, because of course the springs might come from the fissures of the rocks.

4093. (*Chairman.*) Will you now give in the detail of your estimate?—I have made an estimate for the first 130,000,000 gallons to be derived from the No. 1 watershed. The aqueduct I put down at 3,778,114*l.*

4094. Have you made any sections to enable you to make that detailed estimate?—None except those to which I referred in my evidence. I have sections of the sites of the proposed reservoirs.

4095. Then you have assumed the quantities in the other case?—I have got them out as well as I could from the rough section which I exhibited to the Commission on my former examination. Of course, as I said before, this can only be taken as a roughly approximate estimate.

4096. (*Mr. Harrison.*) As an engineer you would not absolutely pledge your reputation to this being an estimate for which you would complete those works?—I think I might do so safely.

4097. (*Chairman.*) Have you allowed yourself sufficient margin to carry you over any contingencies that might arise?—Yes, I think so.

4098. I suppose you have had regard to the Ordnance map?—Yes; I have availed myself of all the information I could get in every shape and way, both with reference to the Ordnance maps, the Ordnance levels, the levels of railways and canals, and other levels.

4099. (*Mr. Harrison.*) Does your estimate give any details?—No; if you will allow me I will hand in my estimate.

The witness delivered in the following estimate:

Estimate of first 130 million gallons.

	£	s.	d.
Aqueduct - - - -	3,778,314	0	0
Reservoirs, &c., in No. 1 watershed -	400,000	0	0
Service reservoirs, pipes from service reservoirs to London, and alterations of existing works - - -	970,000	0	0
	£5,148,314	0	0
Contingencies 10 per cent. -	514,831	0	0
	£5,663,145	0	0
Land and compensation -	470,000	0	0
	£6,133,145	0	0
General expenses, interest during construction, &c. - - -	866,855	0	0
Total - - -	£7,000,000	0	0

Estimate of additional 100 million gallons.

	£	s.	d.
Additional inverted syphons - -	520,000	0	0
Reservoirs, &c., in No. 2 watershed -	330,000	0	0
Service reservoirs, additional piping to London, &c. - - - -	640,000	0	0
	£1,490,500	0	0
Contingencies 10 per cent. -	149,050	0	0
	£1,639,550	0	0
Land and compensation -	180,000	0	0
	£1,819,550	0	0
General expenses, interest during construction, &c. - - -	180,450	0	0
	£2,000,000	0	0

4100. (*Chairman.*) I see you give two estimates, the first showing what would be required for the collecting and storing and conveying of 130,000,000 gallons per diem?—Yes.

4101. Then you add a supplementary estimate for an additional 100,000,000 gallons per diem?—Yes, but I did not intend to have entered upon that, it is not got out with the same care with which the first estimate of 130,000,000 gallons has been got out.

4102. Then your estimate as a whole for 230,000,000 gallons would be 9,000,000*l.* sterling?—Yes; that is considering in the first instance that the aqueduct is taken as of sufficient capacity to convey the 230,000,000 gallons with the exception of the syphons and the reservoirs.

4103. Did you state in your last evidence the point where you propose to form your reservoir near to the metropolis?—I did state that it was to be near Totteridge. There is a very desirable site there I consider for a reservoir comprising about 400 acres of ground, and which I described as being about eight miles from the Marble Arch.

4104. What is the height of the reservoir above datum?—The height of the water level will be about 276 feet above Ordnance datum.

4105. Is it a clay soil there, or would you have to puddle?—It is all clay.

4106. What is the estimate per acre for the land?—I estimate it at 400*l.* an acre at that distance from London.

4107. (*Mr. Prestwich.*) Is it all grass land?—Yes, and there are no houses upon it. I do not think there have been any new houses built near there for years.

4108. When you finish your works at Totteridge have you in your scheme provided any mains or arrangements for the purpose of bringing the water to London or for distributing it when it is brought?—I should connect it of course with the different companies' systems of pipeage which now exist.

4109. But you would not sacrifice your 276 feet by bringing your water down to a lower point, would you; you would not bring it to Thames Ditton for example?—It would be so arranged that wherever a connexion took place with the present system of pipeage the pressure of the water would be calculated to the extreme height of the district; except the amount by which it might be reduced by friction, the pressure would be the same at similar levels throughout the whole present system of pipeage.

4110. But the companies have to pump, as you are aware, from the Thames valley; and if you bring your water and discharge it into their reservoirs it is quite clear you lose your pressure?—But I should not think of bringing the water into their reservoirs. As I said before, the existing pipeage would be connected with the service reservoir, and the pressure at similar levels would be universally the same throughout, except the amount to which it might be reduced by friction or by partially shutting off the water in certain districts so as to prevent danger from excessive pressure.

4111. My point is whether you intend to bring your water by means of iron pipes and utilize your head of 276 feet, and attach your pipes to the pipes of the companies, and thus sustain your pressure, or whether you propose to bring it into the reservoirs and therefore lose your pressure?—No, not the latter, certainly; all present pumping below the level of the proposed service reservoirs would be entirely done away with, and I should thereby secure a very large saving of expense.

4112. How do you connect it with the service of the present companies?—There would be mains which would be taken from the service reservoir to the different existing systems of pipeage.

4113. Then you would distribute it to certain points?—Yes.

4114. Have you directed your attention to the necessary arrangements to be made by the existing companies?—I have considered the thing generally, but not of course in detail. I may just remark, and

H. H. Fulton, Esq.

30 May 1867.

which would exemplify the thing to a considerable extent, that the Grand Junction Company propose to pump their water up to an elevation of 265 feet at Shoot-up-Hill, which is only 11 feet lower than the point at which the level of the water at my service reservoir would be, so that it would be simply to connect my service reservoir with the Grand Junction mains, and the company would then be placed by gravitation in the same position as if their proposal of pumping to the great elevation of 265 feet were carried out.

4115. But how do you propose to deal with the existing water companies with regard to their capital?—That I have not gone into at all.

4116. When we find you at Totteridge with the water from your Welch district you are there a wholesale dealer; you have no connexion whatever, have you, with the existing water companies?—There would be a physical connexion as I before described; but as a matter of policy I have not gone into it at all; I have simply looked at the thing in an engineering point of view.

4117. Does no scheme occur to your mind with respect to that?—None that I should like to enter upon.

4118. (*Mr. Harrison.*) In your estimate, taking the third item you say, "service reservoirs, piping from "service reservoirs to London, and alterations of ex-"isting works, 970,000*l.*;" what are the particular alterations there you referred to?—It would be necessary, of course, in order to distribute the pressure in an economical way to make certain alterations in the different existing systems of pipeage.

4119. Is that based upon any detailed calculation of what the expense would be?—As detailed a calculation as I could make without having proper surveys.

4120. It does not go into the question of the necessary alterations of houses in order to take the constant supply?—No, it does not include that at all. So far as the present system of house supply is concerned I have not attempted to deal with it; as to the conversion of the present system into a system of constant supply, I have not included anything in my estimate for that. By the arrangements which I propose the supply could either be made upon the constant system or intermittent as at present; what I mean to say is, that there is nothing connected with this plan which would prevent the adoption of the constant system, if that were thought desirable.

4121. (*Col. Harness.*) But in taking that 970,000*l.* have you entered into detail so far as to consider how you would communicate with each company?—In a very general way; I could not deal with that question in detail without having a great deal of information which I am not at present possessed of.

4122. But as far as you could you dealt with each company's works separately?—Yes.

4123. And, therefore, you selected a point of junction with each company's works?—Yes; there are several ways by which it could be done, which I think would be of equal cost, but which of those ways would be the best I have not yet decided.

4124. (*Mr. Prestwich.*) What will be the width of the line of land that you will have to purchase for your aqueduct?—That would depend entirely upon the depth of the cutting, the width of the embankment, and whether the aqueduct was in tunnel or not; wherever the aqueduct is in tunnel, the usual way is merely to purchase an easement through the lands through which the tunnel goes.

4125. You have given us the length of open aqueduct; what upon the average would be the width of land for your aqueduct?—On the average, when it was covered or in tunnel, it would be about 40 feet I should think.

4126. And in aqueduct would it be the same?—No; I have not gone into it in that way, I am only giving it roughly.

4127. (*Mr. Harrison.*) Are there not some lead mines which you will have to deal with in your district?—There are only two, I think; there is one about four miles below Plynlimmon on the river Wye.

4128. (*Chairman.*) What is the extent of that mine?—It is not a very extensive mine, and I understand that within the last few months it has been given up on account of its not being remunerative.

4129. Do not the washings from that mine find their way into the river Wye?—Yes, as I stated in my evidence on the last occasion, but the washings from the works which are commenced there will be diverted.

4130. How would you deal with it?—I should simply divert it along the side of the hills and prevent its running into the reservoirs.

4131. You must have a culvert running parallel with the river all the way; where would you propose to take it?—Wherever the point of abstraction was I should take it below that point in a pipe or open drain.

4132. Have you considered the cost of that?—It would be a very trifling affair.

4133. Are there no means of getting rid of it by settling tanks?—I have not calculated upon that. I think, physically, it could be got rid of in the way that I speak of.

4134. (*Col. Harness.*) What would be the quantity of water from those washings which you would have to provide for?—It would be very small. I could not tell what the quantity would be; a comparatively small drain would take it away.

4135. (*Chairman.*) Where is the other mine?—There is one in the watershed No. 1, at Nantycar in the Claerwen valley.

4136. What is the extent of the working there?—I do not think they have been working there very long; the workings are very small.

4137. Do you know how many men are employed in that mine?—I think there are about 15 men, women, and children employed.

4138. Do you propose to deal with this mine in the same way as the other by diverting its water and carrying it to a point where it would not contaminate the general stream?—Yes.

4139. (*Mr. Harrison.*) What do the people at the point where you discharge all that water say to it?—If they were injured in any way they would of course be entitled to compensation.

4140. Do not you think that it would be a matter of absolute necessity to get rid of it by means of reservoirs, that is to say, running it into reservoirs and allowing it to settle instead of carrying it and discharging it into the river below?—I have no doubt that that might be done, but I cannot say that I have gone into that question, because I thought it could be dealt with in the way I propose. I have only looked at it as an engineer; of course the water might be diverted.

4141. (*Chairman.*) In point of fact it is only a question of expense?—Precisely so.

4142. (*Mr. Harrison.*) Could you give us the prices at which you have estimated your work?—The earthwork I have taken at 1*s.* 6*d.* a yard; the excavation in tunnel at 5*s.*; the lining for the open aqueduct I have taken at 1*l.* per foot forward; the brickwork I have taken at 22*s.*, and the concrete at 7*s.* 6*d.*

4143. What concrete would you use, concrete in cement or what?—Concrete in lias lime.

4144. (*Chairman.*) Do you think that 5*s.* per cubic yard is sufficient to carry you through your tunnel?—I think so as an average price. The brickwork in the tunnel I have taken at 30*s.*; the concrete in the tunnel I have taken at 10*s.*; and the bridges, culverts, and fencing I have taken at 2,400*l.* a mile for 161 miles.

4145. Do you mean bridges to connect the lands severed by your cutting?—Yes.

4146. (*Mr. Harrison.*) What have you allowed for the pipes where you cross valleys?—The pipes I have taken at 7*l.* 10*s.* a ton.

4147. Is that for the pipes fixed in their places?—

Yes, fixed in their places, but not including the cost of excavation.

4148. Do you propose to have them submitted to any process for protecting them?—No.

4149. Would you lay them down merely as they came from the foundry?—Quite so.

4150. Does that embrace the whole of the large items?—Yes, those are the whole.

4151. (*Chairman.*) Are you of opinion that the boiling of the pipes and covering them with a solution is a failure?—Really that is a very abstruse chemical question which I am not prepared to enter upon. I have heard discussions amongst chemists of great eminence who seemed totally to disagree with regard to the different mixtures which are in use.

4152. That mixture does not prevent the oxidization of the metal?—I do not presume to say that, because I really do not know.

4153. Is your doubt with regard to their endurance or what?—I am only guided in my opinion by the result of experience in other cases where pipes have been in use, and they have not been found to corrode to any injurious extent.

4154. Does that apply to pipes not covered or coated?—The pipes in London are all laid down without undergoing that process. The West Middlesex Company are at this time laying down pipes of large size which are not coated in any way.

4155. Yours would be very soft water; would that have any effect upon the pipes?—It might do so, but that is also a chemical question upon which you might get much better information from other parties.

4156. At all events it forms no item of your estimate?—No, it does not. There are one or two things which I should like to refer to, which are in the heads of evidence with regard to soft water. I think that one of the strongest instances that I know of where soft water is sought after and appreciated to a great extent by the poor people is a case in the neighbourhood of London. At Hammersmith and the adjacent district there are three or four artesian wells from which they get water, and the proprietors of these wells sell the water, and it is taken about in butts and sold to the poor people at 1*s.* 6*d.* or 2*s.* per butt, or in small quantities a halfpenny a pailful. I have made inquiries about this and I find that they take this water because it is soft they say, and although the company's water is laid on to their premises yet they would rather pay a halfpenny a pailful for this water to make tea and for washing purposes than use the company's water.

4157. Do you know whether the water is soft?—So I am told. I have used some of it for washing and found it certainly very soft, but I have had no chemical analysis made of the water.

4158. May not the poor people to whom you refer buy it under the impression that it is spring water?—No; they buy it on account of its softness. There are a great number of laundresses in that district, and they use it for washing purposes. I think that is the best practical example of the appreciation of soft water.

4159. (*Mr. Prestwich.*) Is the water obtained from beds under the London clay or from the chalk?—The depth of the water in the wells is some 315 feet. I do not know whether they reach the chalk, but I should think it probable that they would just reach the chalk.

4160. Then those waters would be soft, not from the absence of mineral matter but from their containing salts of soda, like the water in the artesian well at Charing Cross?—I do not know how that might be, you are better able to give an opinion upon that point than I am.

4161. It would not be analogous to the water from Wales, would it?—I cannot tell, of course, the origin of the softness, but I know that the water is soft to the feeling. I only mention this to show that those poor people do greatly appreciate the value of soft water, and will use it if they can possibly get it, even by paying very enormously for it, for I consider 2*s.* per butt is an enormous sum for them to pay, it being about 26 times the price of the water supplied by the water company.

4162. But those waters from the presence of salts of soda may have a detergent effect apart from the purity of the water such as that which you would propose to introduce, it may have a natural action?—Yes; but what I wish to show is that those people consider this water soft, and no doubt it is soft for washing purposes, and they appreciate the advantages of that to such an extent that they pay this large sum for it. I have not had the water analysed, and am not at all acquainted with the ingredients which it contains.

4163. (*Chairman.*) Except the fact that you know it to be soft?—I know it to be soft from the feeling. I have not tested it in any other way.

4164. (*Mr. Harrison.*) What Mr. Prestwich points to is very obvious, that they attach great value to this water for a special purpose, that is, for the purpose of washing?—Yes, and for making tea.

4165. And Mr. Prestwich explains what the composition of that water is which makes it peculiarly applicable for that special object?—I have no doubt Mr. Prestwich is perfectly right.

4166. (*Mr. Prestwich.*) All these waters are very uniform in their composition, and it is very probable that the presence of salts of soda may produce a direct effect?—No doubt, but I should like to draw attention to one point which is very often referred to by the advocates of the present supply, which is this: You constantly hear it said that the water is softened by boiling; in almost every chemical analysis which has been made of the Thames water it has been stated that the water would be reduced to three or four degrees of hardness by boiling; but the real meaning of that is this: as I have said before I am no chemist, but I conceive the water must be raised to the boiling point, then allowed to cool, and the carbonate of lime to precipitate before it is soft; then of course it might be used afterwards as soft water, but that would be a most expensive process for poor people to adopt in order to get soft water.

4167. (*Chairman.*) Your point is rather this, is it not? It is true you have water of, say, 14 degrees of hardness, but as so large a portion of that water is used for washing purposes after being boiled, the hardness in point of fact in practice is reduced to from three to five degrees of hardness?—If that were the case I cannot see why those people about Hammersmith who use water for washing purposes should prefer this water to which I have been referring to the water which they get from the water companies. As a rule I do not think that the company's water is raised to the boiling point for washing purposes. This soft artesian well water is sold by the butt, which contains about 110 gallons, at 1*s.* 6*d.* and 2*s.*, as I before stated, dependent upon the distance from which it is carted from the well.

4168. (*Mr. Prestwich.*) I would remind you that those waters are much more impure actually than the Thames water?—Yes, that may be so. The only reason I have for drawing attention to that water is to show that the people conceive this water to be soft, and no doubt they find it soft, and they find an economy in using this water both for making tea and for washing purposes, and I contend that if soft water could be brought to London people would very much prefer soft water to any other which could be supplied to them.

4169. (*Chairman.*) You mean for those purposes especially?—Or for any purpose; I may say that I should have made it a point to have had the River Wye waters and the waters about London analysed in order to have furnished information, as to their composition, but it was intimated to me that the Commission contemplated having all these waters analysed.

4170. (*Mr. Prestwich.*) I think you stated before that you had not had the waters of your district in Wales analysed?—No, for the reason I have mentioned. I should have had them analysed, and I was in communication with some of the most eminent chemists

H. H. Fulton, Esq.

30 May 1867.

with the view of having it done, but I was informed that the Commission would have them analysed.

4171. (*Chairman.*) We have had samples taken on Mr. Bateman's gathering ground. You do not apprehend, do you, that there would be any difference in the chemical properties of the waters on the one side of the hill and on the other?—It would be more satisfactory to me if the waters on both sides of the hill were analysed. It is an important point, and I should have been very glad to have given the information to the Commission if I had not thought that they would obtain it in some other way and from what they might consider a more reliable source. I may observe that I have taken up samples of the River Wye water, and have kept them in bottles since the 14th of September last, and the water appears to be entirely free from any smell or any trace of putrefaction. Perhaps I may be allowed to state that as regards the sparseness of its population the Wye Basin compares very favourably for water supply purposes with the other large river basins of England and Wales; thus while the Thames above Hampton contains a population of 224 to the square mile and the Severn above Tewkesbury 378, the Wye above Monmouth only contains 97 per square mile.

The witness withdrew.

T. Orton, Esq.

THOMAS ORTON, Esq., examined.

4172. (*Chairman*). You are medical officer to the Limehouse District Board of Works, I believe, and you have held that appointment for some time?—Yes, between seven and eight years.

4173. You were actively engaged in the discharge of your duties during the time of the recent outbreak of cholera in that district?—Yes.

4174. Will you state to the Commission your views as to the cause of the outbreak in that particular locality?—To do so it will be necessary to explain a little previous circumstances, and I will be as brief as I can in doing so; during the excessive high temperature in June and the commencement of July I was quite prepared, from experience, for an outbreak of fever.

4175. What were the premonitory symptoms that led you to that conclusion?—The excessive temperature and the strange dry atmosphere; I found that people generally complained of it. They complained, moreover, of peculiar sensations arising from this state of the atmosphere, such as a burning in the throat, and a disposition to sneeze without any cold, and symptoms of that character, which were unusual and which they had never before experienced. However, instead of fever, for which I was prepared, an outbreak of cholera occurred, and this circumstance led me to watch the disease more minutely in relation to its cause than I otherwise should have done; I found that the cholera had commenced in the fever districts, and more especially in those localities where I had always found fever, and amongst that class of people who are more particularly subject to fever; I was in doubt at first as to the cause of it. The Registrar-General had given out that the water was the origin of the cholera, and the impure water from the East London Waterworks at Old Ford more particularly.

4176. You first referred to the condition of the atmosphere producing great dryness upon the surface of the skin and creating a tendency to sneeze, or a kind of influenza sensation; can you at all account for that condition of the atmosphere locally?—It was generally regarded by the parties who had spoken of it to me as atmospheric; that there was something unusual in the atmosphere which had caused those unpleasant symptoms.

4177. Why should those terrible results follow in that limited area and not in other parts of the metropolis, if it were merely atmospheric, unless the cause of the condition were local?—I believe it was principally local.

4178. Arising from what cause, in your judgment?—There were a great number of sources of nuisance at the east end of London, more particularly about Bow Common and the river Lea at that time, which gave rise during that excessively hot weather to foul gases and noxious effluvia.

4179. Then in your opinion it was a combination of causes rather than any single cause?—Yes, owing to the foul gases and the fearful vapours which were carried by the north-east wind which prevailed for several days in the direction from this field of nuisances; I may say nuisances, because it was not only the river Lea at that time, but numerous factories all within the area to which I am now referring.

4180. (*Sir B. Phillips.*) Were those symptoms of which you speak limited to any particular class of people?—No, they were general.

4181. (*Chairman.*) Was it the water do you think that had any effect upon the constitution to produce those symptoms?—No, I have no reason to think anything of the kind.

4182. You are rather inclined to the view that it was atmospheric?—Yes, it was atmospheric at first.

4183. Produced by a variety of causes, including the drainage, and I suppose that that is a part where the main drainage is not completed?—Just so.

4184. Do you think that the water had anything to do with it?—I am very much disposed to question it. At first I was disposed to coincide with the Registrar-General, because I was utterly at a loss to account for it; but as time went on from day to day, watching it closely as I did, I came to the conclusion that the water had little or nothing to do with the matter.

4185. You have two distinct waters supplied there, have you not?—Yes.

4186. Will you describe those waters?—One is from the Old Ford reservoir, and the other is from a reservoir higher up.

4187. It is the Old Ford water, is it not, which is alleged to be so impure?—Yes.

4188. Have you carefully watched the area supplied by the Old Ford water as contrasted with the area supplied from the higher source?—Yes, I have.

4189. What has been the result of your observation?—I found that in the area supplied by the Old Ford water the disease was very remarkably more prominent.

4190. How do you account for that fact?—I account for it in this way, that the Old Ford water supplies those districts more immediately coming within the operation of those nuisances through the north-east wind.

4191. (*Sir B. Phillips.*) You attribute it rather to the district to which the water is supplied than to the water itself?—I do not altogether say that the water has nothing to do with it; I would say it has very little to do with it. I think that the nuisances on Bow Common and the river Lea at that time had a very great deal to do with it.

4192. You have seen the report of the Registrar-General, have you not?—Yes.

4193. You saw that he spoke very strongly as to the effects of the water?—Yes.

4194. (*Chairman.*) You made a report to your board, did you not, on the subject of the cholera?—Yes.

4195. What is the quality of the Old Ford water? In your judgment is it suitable for domestic purposes?—I have not gone into the analysis of the water, I have left that to those able chemists who have made so many analyses of it; but as a rule I have not found the water complained of generally, and during the time of the cholera very numerous families known to me drunk that water with impunity.

4196. It has been stated that a certain leakage took place from one of the cuts into the reservoir supplying the district with water; have you any knowledge of that fact?—I believe it was the fact, indeed I know it was; I was down at the works at the time it was discovered.

4197. Would not that have a very serious depressing influence upon the health of the inhabitants?—There is no doubt that it would have a depressing influence upon the inhabitants; all impure water is so far injurious.

4198. (*Sir B. Phillips.*) You are a general practitioner, I presume?—Yes.

4199. In your experience among your patients generally, did you find any instances of the deleterious quality of this water during the progress of the cholera?—No, excepting amongst a certain class and in a certain locality. The poor and impoverished people living in certain habitations were the class more especially obnoxious to cholera.

4200. And you found that those people who were living in very inferior habitations, badly fed, badly clothed, and intemperate in their habits, were the classes of people who were more liable to be attacked and struck down by the cholera than others?—I did.

4201. And you attribute to those causes rather than to the water the prolonged outbreak of the cholera?—I consider that those causes made them susceptible of the choleraic poison whatever it may be.

4202. You think that the patients had less power of resistance when they were attacked?—Yes, just so. But amongst the better classes who were intemperate whatever might depress their power of life, intemperance, or fatigue of body or mind, or any excesses, if they were in a bad state of health, they would also be susceptible of the disease; but those in a good state of health, living temperately, amongst the better classes I do not find as a rule were at all susceptible of the disease.

4203. (*Chairman.*) We are to understand that there were a variety of causes in operation to produce a general depressing influence on the health of the inhabitants?—Yes.

4204. And thus to reduce the resistant force of the constitution?—Yes.

4205.—And when the disease made its appearance they became easy victims to its power?—Yes.

4206. But are you not able to say whether the water was an important element in the production or increase of the cholera?—I cannot positively speak on that point. I would rather speak in the negative sense in reference to the water producing the cholera.

4207. But yet you do speak to the fact that the water supplying that larger area was contaminated by leakage from one of those leaky cuts?—Yes.

4208. Would not that in itself be sufficient to account for a vast amount of disease?—Yes, but I must observe that the leakage in the reservoir may have been, and I believe had been, going on for some considerable time, perhaps some years, unknown to the company.

4209. And I suppose that that in itself would be sufficient to account for a great many zymotic diseases which have been prevalent in that locality?—Yes, there is no question that it would aggravate them.

4210. (*Mr. Harrison.*) I think you describe it pretty fully in page 12 of the pamphlet which you have handed in, which is a special report by you to the Limehouse District Board of Works; you say "Now "whatever dispute there may be about the origin of "the cholera and its relation to the water supply "there can be none as to the localities where it has "found victims. In the parish of Limehouse there "are nine streets with 100 deaths; in Ratcliff "seven with upwards of 60. One character runs "through the whole of them as a rule; like Eastfield "Street, North Street, and Northey Street, Lime-"house, and William Street, Ratcliff, they are "either built over slush and filth, or the flooring and "joists rest on the earth itself or but a very few "inches above it. These are the places where "always has come fever just as they have lately been "in turn the fatal resorts of cholera." I take it from that that your view is that this unhealthy habitation is much more likely to breed cholera and a much more certain element of it than any question with regard to the water supply?—Most emphatically I say so.

4211. (*Chairman.*) Has your attention been directed to the mode of storing water by the poor in those localities?—Yes, that has come under my supervision.

4212. They keep it in tubs, do they not?—No, not in tubs, in water butts or tanks.

4213. Are the houses generally supplied with cisterns?—Yes, with cisterns or water butts; no tubs are allowed—we never allow it.

4214. When you say "we" do you mean the district board?—Yes, the Limehouse district board, at my suggestion.

4215. Are you of opinion that the constant supply would be a preferable mode of distributing water to the intermittent system?—Decidedly.

4216. What are your reasons in favour of that view?—I think that the storage of water by the poor more particularly is objectionable in itself, and renders it liable to contamination as well as from the decomposition set up, especially in hot weather.

4217. The water itself would have the power, would it not, to absorb the gases which are generated in that locality?—Just so.

4218. (*Sir B. Phillips.*) You recommend, do you not, in your report that certain streets, courts, and alleys should be wholly demolished as incapable of sanitary repair and unfit for habitation?—I do.

4219. And that all factories, yards, and works of every description engaged in operations on animal matter or giving rise to offensive effluvia should be at once abolished?—Yes.

4220. That is really the conclusion at which you have arrived?—Yes.

4221. In fact your idea appears to be that the disease is rather generated by those influences of which you speak than by anything connected with the water?—I think that atmospheric causes have had mostly to do with it, in combination with the nuisances of the locality, and not the water itself.

4222. And this is the remedy which you propose?—Yes; those are amongst the remedies. There are streets in my district where it is impossible to keep out fever whenever it shall become epidemic. They are built upon filth. Perhaps the Commission will allow me to give an illustration of this as bearing upon the point. In the Burdett Road, Limehouse, there are perhaps 300 houses built fairly on a good foundation, and little or no cholera was to be seen there. A little way off, about a short quarter of a mile, there are about 120 or 140 houses, four-roomed houses occupied by mechanics and that class of people, and they are built as it were upon the earth. There is no exaggeration in the report which I have made. I there found that the cholera was fearful; there were numerous deaths, and diarrhœa was very prevalent; whilst in the Burdett Road, only a short distance off, there were scarcely any cases.

4223. (*Chairman.*) They have a sewer down the Burdett Road, have they not?—Yes, they have.

4224. And the basements of the houses are all drained?—Yes. In an adjoining district some years ago there was a quantity of gravel taken out and a large pit left. An invitation to fill this pit up was issued by the owners of the property by giving the men a ticket for beer, and this immense place was very soon filled up with all kinds of filth, and it has since been built over and occupied. I say that the slaughter of human life there was frightful.

4225. Our inquiry is specially directed to the question of the quality of the water, and I understand from your statement that you are of opinion that the water was not the principal cause of the outbreak of cholera in that district?—Just so.

T. Orton, Esq.
30 May 1867.

4226. But that it is due to other causes, or rather to a combination of causes?—Yes. Perhaps you will allow me to say further, that in the Limehouse establishment for children last summer they were drinking water, as the master tells me, all day long, because they had nothing else to drink, and there was not one case of diarrhœa or cholera.

4227. How many children were there in that establishment?—400.

4228. Were they drinking the Old Ford water?—Yes.

4229. Was it subject to any filtration?—None at all. There is an iron ladle attached to the tap, and they were drinking all day. In the Stepney union at Bromley there were 700 or 800 persons drinking this Old Ford Water in a similar way, and there were not more than three deaths from cholera, and those arose from the parties going out to Shadwell to nurse some friends who were then suffering from cholera, and they brought it back with them; and those were very aged people, as I have mentioned in my report, whilst round about this very workhouse where the houses are built upon the wretched foundation which I have described, there were numerous deaths. It was fearfully felt there, and just round about the Limehouse workhouse in the same way the mortality was very great. In the Poplar union again I am not aware—and I saw the medical officer yesterday, and he was not aware—that there was one death in the Poplar union workhouse, whilst round about in those houses so wretchedly built there were numerous deaths.

4230. (*Sir B. Phillips.*) Are you the only medical officer for the Limehouse district?—Yes, I am the only medical officer.

4231. What is the population in your district?—Nearly 60,000.

4232. (*Mr. Prestwich.*) Are there not equally wretched localities in the district supplied by the upper reservoir of the East London Company?—I am not acquainted with them, but the houses of this class that have been built about London have much of the same character.

4233. What I want to know is whether you have districts equally wretched in that part of London which is supplied by the other reservoir, and whether you found the cholera to be more or less prevalent there?—I have no knowledge of the other districts, I confine my observations more particularly to my own.

4234. Your duties do not go beyond the Limehouse district?—No.

4235. (*Chairman.*) Is there anything further that you would wish to suggest to the Commission?—There is one point that I should like to mention to the Commission. In the third week of July the chairman of the Sanitary Committee said to me: "When will this fearful mortality end? When will "there be a change in the disease?" I said, "I will "stake my reputation that immediately the wind "shifts to south south-west and rain comes it will "subside."

4236 And was that prophesy realized?—Yes.

4237. I suppose it was based upon previous observation?—Yes.

4238. (*Sir B. Phillips.*) How long have you been medical officer of your district?—Between seven and eight years.

4239. (*Chairman.*) And did that dryness of the skin and the other symptons depart immediately the wind changed?—It all gave way, and people, as I have expressed it, breathed more freely, and felt a relief as if something had left them. The chairman of the district board is quite ready to confirm that; in fact, I have mentioned it in my report.

The witness withdrew.

S. W. Leach, Esq.

STEPHEN WILLIAM LEACH, Esq., examined.

4240. (*Chairman.*) You are the engineer, as we are aware, to the Thames Conservancy Board?—Yes.

4241. How long have you held that appointment?—Under the conservators and under their predecessors, the corporation of the City of London, for about 25 years.

4242. As engineer, you have had your attention naturally directed to the condition of the river Thames?—Yes, I have.

4243. And to the volume of water now abstracted from the river for the purpose of supplying the inhabitants of the metropolis?—Yes, I have.

4244. Have you observed any evil effects of that abstraction of that water upon the scour of the river?—No, I have not.

4245. Are the companies working up to their statutory limit, or have they power to take a larger quantity than they now take?—They have power to take a considerably larger quantity than they have ever yet taken.

4246. And do you apprehend any evil arising to the volume of the river, supposing they were to exercise their power to the extent that Parliament has authorized?—I do not.

4247. Do you think that the Thames basin and the Thames stream are equal to the growing requirements of the metropolis?—Yes, I do.

4248. Do you mean the Thames, in its present condition, apart from any question of storage by means of reservoirs?—Yes, I think that reservoirs would be valuable auxiliaries; but I was about to say that for the greater part of the year the largest abstraction that the water companies can make could not be detected in the volume of the river.

4249. Have you made a section of the river at any point and gauged the daily flow?—Yes, I have.

4250. At what point?—At Teddington, below the lock.

4251. Have you any tables showing the daily flow?—Not showing the daily flow, but I have a register.

4252. How often have you taken the quantity?—I have occasionally gauged the flow of the stream, and I have had daily observations made which give me the height of the water. I do not mean to say that I have worked out those observations to show what the daily flow is, but they give me a very good idea of what quantity of water is passing.

4253. If you have made a careful section of course the height of the water would give you the volume flowing?—Yes.

4254. And have you tested that so that it could be worked out to give the number of gallons passing that point daily?—Yes, but it would be far better done at a weir.

4255. But they have no weir sufficiently perfect to enable you to do that?—No, the Teddington lock was constructed merely with a view to navigation and not for gauging purposes.

4256. Consequently a great deal finds its way through which you cannot gauge?—Yes, it is so very irregular that it cannot be done.

4257. Are you aware of the fact that Mr. Simpson has made a section of the river above the point where the water companies are taking the water, and has made very frequent observations?—Yes, he has daily observations taken, and has had for many years past.

4258. Have you compared your observations with his?—No, I have not compared them; at least not recently. A good many years ago I did.

4259. Can you speak at all from your observations as to the minimum quantity flowing at Teddington?—The minimum quantity that I have ever gauged has been 380,000,000 gallons in 24 hours.

4260. Have you gauged the river in flood, so as to know the maximum?—No, I have not.

4261. Have you taken the mean condition of the

river?—No, a low condition of the river; I will not say the lowest, but a decidedly low condition of the river.

4262. I suppose that two or three times the quantity you have mentioned would come down in flood?—Yes, and more than that.

4263. (*Mr. Harrison.*) Is that the quantity above or below the point where the companies take their supply?—Below.

4264. (*Chairman.*) Have you gauged the stream at any other point?—I have gauged it just below Kew Bridge.

4265. Are there any tributaries between that point and Teddington?—There is one branch of the Colne, and of course there are the springs which would rise in its course over about six miles; I gauged it at Kew Bridge in the beginning of October 1865, which was a dry season.

4266. Is the difference considerable between Kew and Teddington?—It was somewhat over 450,000,000 gallons when I took it at Kew, which was six miles below Teddington.

4267. There would of course be more water in the river there than at the upper point?—Yes, one would reasonably expect there would be much more there.

4268. (*Col. Harness.*) Do you know what the volume was that was then flowing at Teddington?—No, I do not, on that day.

4269. (*Chairman.*) Having regard to the increase of population in the metropolis, and the increased use of water by substituting waterclosets for cesspools, and other sanitary arrangements, you have no doubt that the Thames basin is equal to supply the whole of the metropolis?—I think so.

4270. And that it might be so taxed without injuring the scour of the river?—I think so.

4271. Are you of opinion that it is or is not necessary to have those auxiliary aids, such as storing in time of storm in reservoirs at different points?—I think that they would be desirable auxiliaries, because you would be utilizing a quantity of water which now runs to waste, and you would unquestionably assist the volume of the river materially in very short water time.

4272. What is the effect that is produced in the lower or tidal part of the river by those floods?—To scour the channel of the river; we notice that the large quantities of mud that collect on the foreshores during summer time are carried away by the winter floods.

4273. Have you observed the effect of the floods below London Bridge in the Pool?—Yes; a land flood has a decidedly cleansing effect there, and very particularly when it is connected with ice.

4274. (*Col. Harness.*) Are there not deposits in other parts of the river from the land floods instead of a scour?—There is a slimy deposit on the land which the flood waters cover, but I do not think there is anything beyond that.

4275. You do not observe that there is any material deposit?—No.

4276. (*Chairman.*) Do you think that by the principle of storage and equalizing the flow of the river you would lose the benefit of those special scours to which you have made reference?—No, I do not think we should.

4277. You think that you might store sufficient water to give an ample supply, and yet have the benefit of those floods for scouring purposes?—Quite so.

4278. Are there any points up the river which are peculiarly suited in your judgment for the formation of reservoirs for storing?—Yes; there is a district beyond Oxford which is well qualified for the formation of reservoirs.

4279. Is it a clay district?—Yes.

4280. How many miles is it above Oxford?—I think the most eligible point would be about 10 miles beyond Oxford.

4281. Then you would fill your reservoirs from the river itself when in flood?—Yes.

4282. And then you would store it and allow it to flow when the water went down or the supply was deficient?—Quite so.

4283. Would there be any difficulty in keeping the water in a state of purity all the time?—I think not if the reservoirs were made as they ought to be made, sufficiently deep, and I would have them made very deep, certainly not less than 20 feet in depth.

4284. And do you think that at that depth the water would sustain itself in purity?—I think it would.

4285. I presume the object of having it deep is to avoid the decomposing effect of a high temperature?—Yes; when the water becomes warm there is a great tendency in the weed to grow, and when it is shallow the light gets better access to the weed also, and that tends to make it grow.

4286. But with a depth of 20 feet you think that that would be obviated?—I think it would; and I say so because I have noticed that in parts of the river where the water is very deep, there is little or no growth of weed.

4287. Will the repairs which you are now carrying out at the several weirs and locks up the river have a tendency to improve generally the condition of the river?—I conceive they will have a very material effect in improving it.

4288. Captain Burstal told us that you had served a notice upon all the towns up to and including Oxford requiring them to divert their sewage within 13 months from the date of notice, but of course subject to an appeal for further time if any of them should require it?—Yes, that is so.

4289. It would of course greatly improve the river if that sewage and other contaminating matter were diverted?—It would improve the condition of the river, but I think that the contamination has been very much exaggerated. In those country towns there is no regular system of sewage generally. The majority of the houses drain into cesspools; and really there is no very large outfall in any case except at Windsor; there a more perfect system of drainage has been carried out, and there is a most offensive outfall.

4290. Still there must be a very large amount of ammonia flowing into the river notwithstanding the cesspools, because of the overflow which you must necessarily catch in the river. A cesspool is very soon filled, and though not filled withsolid excreta still there is an overflow, and that must find its way into the river ultimately?—The ground absorbs a good deal of that. I have noticed the outfalls of some of the larger towns, such as Abingdon and Wallingford, and although they are unquestionably offensive, still there is not that volume which would be the case with a similar population in London.

4291. Is the volume of water in the river sufficient to deodorize it?—Yes, it very soon loses any contamination.

4292. Take Windsor for example, where there is a discharge of a considerable amount of sewage out of their drains, have you observed the condition of the river at the point of discharge, and also a few miles down?—Yes I have.

4293. How soon in your observation is the effect of sewage destroyed by its flow and admixture with the water?—At Windsor it is discharged into a most unfavourable point in the river, where there is little or no stream at ordinary times. At times of flood of course there is more stream, but usually there is very little stream there, and the matter which is passed out of the drain floats about in the river there to a very great and very disgusting extent.

4294. Is there an eddy there, or what?—No, there is a weir just immediately below, which deadens the stream sufficiently to deprive it of the force required to take what is floating away. Two miles or even a mile below that I could see no traces whatever of the sewage.

4295. Was it all broken up and destroyed?—Yes, and taken by fish, and so on.

4296. Is it the habit of fish to take up matters of

S. W. Leach, Esq.

30 May 1867.

that kind?—Yes, you generally see persons fishing close to the outlet of a drain. I think that the operation of the Act of 1866, which prohibits the discharge of sewage into the river, will have a very beneficial effect. If some such provision had not been passed I can quite understand that as the system of waterclosets was extended and a more perfect system of drainage was carried out, the river would rapidly become much more contaminated; but the powers contained in that Act will, I hope, put an effectual stop to the pollution of the river.

4297. You are aware that at Kingston they contemplated a regular system of drainage, and pointed their outfall to the river?—Yes.

4298. What steps have they taken to deal with their sewage?—The most recent steps that they have taken have been to attempt to induce Parliament this session to give them a greater time for dealing with the question. I do not know whether they will succeed in it.

4299. Have they a bill before the House now for that purpose?—No, but the conservators have a bill before the House, which they were bound by the Act of 1866 to bring in, prohibiting the discharge of sewage into the river between Staines, where the Act of 1866 ceases, and the western limit of the metropolitan district.

4300. (*Sir B. Phillips.*) By means of storage auxiliaries what quantity of water do you think might be safely taken from the river *per diem*, the water companies being permitted now to take something like 100,000,000 gallons, although they only take 50,000,000 gallons?—They take more than 50,000,000 gallons in the driest seasons.

4301. What quantity do you think they might take?—With storage reservoirs I should think that the river might be maintained in a perfect state if they took 200,000,000 gallons in the 24 hours.

4302. (*Chairman.*) They might take, might they not, the additional 50,000,000 gallons, which they are entitled to take under the Act, without any injury to the river?—I think so. The portion of the river which would be affected by it is very short, varying from three to six miles above Teddington Weir. The whole of the rest of the course of the river would be entirely unaffected by it, so that it is only that limited space which would be immediately affected.

4303. It is the space I presume from the tidal point to the point where they take the water?—Yes; they take it mainly at two different points. There is also the question of interfering with the supply of water in the upper part of the tideway; and I think that more complaint has been made from persons residing in that part than any other of the ill-effects which have been presumed to follow the abstraction of the water. In my opinion they have been quite mistaken upon that, they have attributed to the abstraction of the water from the river that which has arisen from an entirely different cause. The fact is that the Thames in the tideway for the last 30 years or more has been undergoing very great changes. The bed of the river in and about London has been depressed by the excavations which have been made in it, but at the upper extremity of the tideway it has remained pretty nearly the same. The consequence is that the inclination from that point down to where the excavations have taken place has become much greater, and consequently the stream is much more rapid, and therefore instead of the normal flow of the river passing off gradually as it did formerly, it now runs off very quickly, producing a much sharper stream in the upper part of the tideway towards the time of low water than there used to be, and whatever supply there is of water is consequently carried off more rapidly.

4304. You find, do you not, a great improvement in the condition of the river within the metropolitan district since the sewage has been diverted by the works of the main drainage?—There is an immense improvement to the westward of Woolwich, but at the outfalls themselves and below them, the condition of the river has deteriorated.

4305. The volume of sewage discharged is very large there?—Yes, it is inevitable that it should be so.

4306. (*Mr. Harrison.*) Are you aware of any very minute experiments which have been made lately by Mr. Bateman with respect to the quantity of water flowing over Teddington Lock?—No, I am not.

4307. Then you are probably not aware that he has calculated that in dry seasons the quantity does not exceed 305,000,000 gallons?—I have heard it stated so.

4308. But even assuming that to be as an exceptional case the minimum, there would be no difficulty by service reservoirs in keeping that as the minimum under all circumstances, that is to say, assuming that the companies were to take 200,000,000 gallons, you could, by service reservoirs in exceedingly dry seasons, make up that deficiency?—Yes.

4309. Looking to the interest which you have in the conservancy of the river, you would not be at all afraid of allowing the companies to take 200,000,000 gallons, provided they were under the obligation, in case they did take such a large quantity, of bearing the expense of constructing and maintaining the necessary reservoirs to compensate for what they took away in dry seasons?—I think that the condition of the river would bear that perfectly well; it would be maintained under such circumstances in a perfectly good condition.

4310. With regard to the weir at Teddington, I have understood that you are making provision now by which you can accurately gauge the amount of water which will pass over it—is that the case?—No, it would be rather an expensive thing to make it a perfectly good gauging weir; but as it will not be very long before it will require rather expensive repairs, I have no doubt the conservators would approve of a plan which should make it a perfect gauging weir. I think it would be a most desirable thing to have a daily record of the flow of water there.

4311. The companies having at this present moment the power of taking 100,000,000 gallons daily from the river, would you give us your opinion as to whether they could take a larger quantity than that without compensating reservoirs?—I think they might. The part of the river affected by the abstraction is so limited that I think, supposing any inconvenience did arise, which I really do not think would be the case, it might be obviated by the execution of works in the upper part of the tideway which would compensate for any ill effect that might be produced. Such works would consist of deepening the river so as to prevent the water from running off as I have described so rapidly as it does at present, and, of course, the same operation would bring the tide in sooner, and keep a full river longer.

4312. Either by the process of deepening below the weir or by compensating reservoirs above, you consider that there would be no reason whatever why 200,000,000 gallons, if necessary, should not be taken from the river above Teddington?—200,000,000 gallons would be rather an extreme quantity to take without any compensating reservoir, but with compensating reservoirs I should have no question whatever about it.

4313. (*Col. Harness.*) If the minimum flow were retained at its present amount, you think that no injury would be done to the navigation?—I think not.

4314. Even though the minimum flow were continued over a greater number of days?—No, I think that there would be no material inconvenience; certainly not to the navigation.

4315. (*Mr. Harrison.*) You have examined all the upper sources of the Thames, have you not?—Yes, I have.

4316. Is the point you mentioned above Oxford the only one where you think reservoirs could be conveniently constructed?—I think there are other points where they might be constructed, but I am not so sure about the strata at other points being suitable.

4317. You perhaps have not gone into the detail of the nature of such a reservoir or calculated the quantity

S. W. Leach, Esq.

30 May 1867.

which it should hold?—Not minutely. The fact is, that you could not come to a satisfactory conclusion unless you had borings made, and a proper and accurate survey made, and that has not been done yet.

4318. Still you have had your attention sufficiently directed to the subject to give with perfect confidence the answers which you have already given?—Yes. I have looked at that part of the river particularly with reference to this subject, and assuming that the Oxford clay prevails there which is said very confidently to be the case, and which I have no reason whatever to doubt, I think that it would be an advisable place for reservoirs. There is one point which has occurred to me of which the observation of the chairman has reminded me, with regard to the improved condition of the water in the tideway; whether the supply which London requires might not be economised by drawing water from this lower part of the river for watering streets, flushing sewers, and such purposes as that, where it is not necessary to have water of the purest quality.

4319. (*Chairman.*) That would involve, would it not, a duplicate system of mains?—Yes, I am quite aware of that, but the water which is used for watering streets, and those other purposes, has to undergo all that expensive process of filtration which is adopted to render it fit for drinking; and it has to be brought from a great distance as well; and it has often occurred to me that when the condition of the river here should be improved as it is now there would be no harm whatever in taking water from this part of the river and applying it to those purposes to which I have referred.

4320. For street and fire purposes you think it would be quite good enough?—Yes, and for some manufacturing purposes also.

The witness withdrew.

Adjourned to Wednesday next, at 11 o'clock.

Wednesday, 5th June 1867.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.	Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.

JOSEPH PRESTWICH, Esq.

GEORGE REMINGTON, Esq., examined.

G. Remington, Esq.

5 June 1867.

4321. (*Chairman.*) What is your occupation?—I am a civil engineer residing in London.

4322. Are you connected with any society?—I am a member of the Institute of Civil Engineers.

4323. Are you engineer to any water company?—I am not at present. The last position I held was that of Civil Engineer to the Admiralty at Bermuda, and I was there for five years.

4324. Have you turned your attention to the question of water supply to the metropolis?—I have.

4325. Have you done so with the view of procuring it from any particular district?—Yes.

4326. Have you prepared a scheme for bringing it from any place?—I propose to bring it from the hills of Derbyshire, to collect it at a point above Mill Dale, on the Dove, from the summit of the Derbyshire and Staffordshire range of hills.

4327. What is the distance to London from the first point where you propose to take the water?—135 miles.

4328. What height should you be there above Trinity high water?—586 feet above Ordnance datum.

4329. Where do you propose to deliver the water for the supply of London?—On the top of Barnet Hill, about 10 miles from London.

4330. What height would you be at Barnet?—300 feet above Ordnance datum.

4331. (*Sir J. Thwaites.*) Do you mean at Totteridge?—Adjoining Barnet; what is called Barnet Hill.

4332. (*Chairman.*) What tract of country do you propose to get your water from, at the extreme point of Mill Dale or the river Dove? What extent of area do you propose to put under contribution?—262 square miles.

4333. Have you had any rain gauges taken in that district?—No, I have not taken the rainfall.

4334. Would you not consider that to be rather an important feature?—No doubt it would be requisite to determine accurately the quantity of rainfall to know the precise quantity of water to be obtained.

4335. What quantity of water do you propose to supply per day at Barnet Hill?—About 100,000,000 gallons. I have put it down in the paper which I sent in to the Commission as 83,000,000 gallons, or one-sixth of the rainfall on the 262 square miles, but in round numbers I would take it at 100,000,000 gallons per day.

4336. How do you arrive at anything like a conclusion that you could get such a quantity from this district?—By assuming that the rainfall upon those hills is 48 inches per annum.

4337. Is that the minimum rainfall or the mean?—The mean, taking the year through. I assume that to be the average, but I have no doubt that if it were accurately taken it would prove to be considerably more. It has been gauged at Uttoxeter, which is on the Dove, but Uttoxeter is very low, and there the rainfall is about 30 inches, and I have assumed the quantity falling on the high district to be 48 inches.

4338. Do you think that an average fall of 48 inches would enable you to supply 100,000,000 gallons per day at Barnet?—I do, and that is only one-fifth part of the quantity that falls. I only propose to take one-fifth part of the rainfall on those hills, leaving the remainder to flow into the river.

4339. Do you mean that 48 inches is one-fifth of all that fall?—No, I only take one-fifth part of the quantity that falls, and that would give 100,000,000 gallons a day.

4340. Do you mean that one-fifth of the 48 inches is equivalent to 100,000,000 gallons a day?—That is so.

4341. What description of country is it between Mill Dale and Barnet?—I have a section of the whole country through, which I took some years ago when I explored the country for a railway from London to Manchester, and a part of that section I have here, which is upon a very large scale.

4342. Then how do you propose to bring the water?—Partly through pipes and partly through open aqueduct, and partly through tunnel.

4343. What description of pipe?—I consider that two pipes of about 6 feet diameter each would be sufficient to bring that quantity of water to London.

4344. What was the total cost of your plan?—I put it at 5,000,000*l.*

4345. And to take how long in the construction of

G. Remington, Esq.

5 June 1867.

the works?—I have hardly gone into the question of time.

4346. When you get the water to London, what do you propose to do with it?—To distribute it by pipes on the present principle of mains.

4347. What do you intend to do with the existing companies?—I think that the best plan would be for the Government to purchase the interests of the existing water companies.

4348. Assuming that the Government have bought up the existing water companies and you are with your water at Barnet Hill, what is the next process?—The next process would be I expect also that the Government would carry out the new water scheme, and unite the two systems into one.

4349. When you say that, do you mean that the Government should give you 5,000,000*l.* for your water when you have brought it to London?—I mean that the Government should expend 5,000,000*l.* in carrying out the plan to bring the water to Barnet.

4350. Then we are to understand that this is a scheme which you propose that the Government should undertake?—It might be done by private enterprise, but I myself think that the water supply would be better in the hands of the Government.

4351. Dealing for a moment with your scheme by which you tell us you could bring the water from a particular point to London at a cost of about five millions of money, by what parties do you intend your scheme to be carried out, or are we to understand you to say that the Government should do it all?—I say that it might be done by private enterprise, but I think it would be better that the water supply should be in the hands of the Government.

4352. How do you propose to collect the water at Mill Dale?—I propose to erect weirs across the various streams which come down to that point at different levels, and by that means collect all the water that is required upon the usual plan of dams and weirs.

4353. Do you propose to construct any large reservoirs?—Yes, several. I propose to construct reservoirs upon every ridge of hills that I pass through.

4354. What size would the reservoirs be?—Taking them in the aggregate as furnishing 60 days' supply, it would require about 1,000 acres of reservoir space to supply that quantity of 100,000,000 gallons, supposing no rain to fall.

4355. I understand you to say that you would make reservoirs upon all the ridges as you go along; what would be the size of any one of the reservoirs which you propose to make, say the largest one?—I have taken them in the aggregate. I have not calculated the size of any particular one at present, but taking the whole through it would require for 60 days supply a storage of 1,000 acres of water 20 feet deep.

4356. That is over and above what would be in the rivers?—Yes; that would be the size of the reservoirs for 60 days supply supposing there was no rain during the whole of that time. There would be at least 10 or 12 different reservoirs to hold that quantity.

4357. How do you propose to fill any or all of those reservoirs?—By pipes and aqueducts from one to the other. They would descend gradually, and according to the line which I have taken they would be at Battle Flat in Leicestershire, between Burton-upon-Trent and Leicester, where there is very high ground. That would be the first, and from that point they would descend gradually, having a large reservoir upon each of the ridges between the valleys all the way to London.

4358. There appears to be a considerable amount of tunnelling in your scheme. I see you propose 45 miles of tunnel?—Yes; the tunnelling would come as cheap or cheaper per mile than the pipe work.

4359. Would you not require pipes through the tunnels?—In some cases I should, but where the fall is with the inclination I should not.

4360. What you would propose then is a tunnel in which you would have no pipe?—Yes, the water would flow through the tunnels.

4361. But how do you propose to build the tunnels?—Of properly constructed brickwork or masonry watertight.

4362. In your estimate you have put down 3,000 acres of land, but you would require, would you not, to take a great deal more land than 3,000 acres?—No, I think not. The width of the way would not be very much.

4363. Would that include severance and damage?—Yes, I think about that quantity would be sufficient, but I have not gone into the matter very minutely as to the quantity of land.

4364. That might add very considerably to the cost of your scheme, might it not?—Not very much, I think I take it at 60*l.* an acre.

4365. Could you get land at that price, which is not much more than the agricultural value?—In some cases where the tunnelling was the land would hardly require to be purchased. There would only be the compensation for passing through, the surface would remain untouched.

4366. Do you find that generally in constructing railways the proprietors do not want to sell their land if you tunnel underneath?—Of course they require compensation.

4367. Is not 60*l.* a very low figure?—Not for the land that the line would generally pass through.

4368. You talk about going through Leicestershire; is not some of that very rich grazing country?—A part of Leicestershire is.

4369. However, you say you are not bound by that estimate?—Not at all; of course this is only a preliminary approximate estimate, and therefore you must allow a little latitude upon that head.

4370. Will you give us the estimate for your scheme?—Yes. 45 miles of tunnelling at 20,000*l.*, 900,000*l.*; 68 miles of double tubing, including brickwork and masonry for piers, at 30,000*l.*, 2,040,000*l.*; 6 miles of open aqueduct, including brickwork and masonry, at 25,000*l.*, 150,000*l.*; 2 miles of cutting at 10,000*l.*, 20,000*l.*; 14 miles of reservoir, including all work, 50,000*l.*, 700,000*l.*; 8 miles of cutting, embankment, and tunnelling, to unite the rivers above Mill Dale, at 17,000*l.*, 136,000*l.*; embankments, dams and weirs, sluices, &c., 350,000*l.*; 3,000 acres of land at 60*l.*, 180,000*l.*; making together 4,476,000*l.*, and contingencies, 447,600*l.*; forming a total of 4,923,600*l.*

4371. You have made plans and sections as we understand for the whole way from one end to the other?—Yes, I have.

4372. Have you gone into all those figures carefully?—Yes, I have.

4373. Are those the figures which you are prepared to state will be the result of your calculation?—I consider that upon the whole 5,000,000*l.* would be about the expense of carrying out the scheme.

4374. But the 180,000*l.* which you have put down for land you cannot pledge yourself to?—No, but it will make very little difference in point of quantity, I believe.

4375. That you say you have not gone into, but with regard to the works, which is a matter which would come under your immediate cognizance as engineer, you would know whether they could be constructed for that amount which you have put down?—Yes, I consider that the prices generally which I have put down would be ample.

4376. Have you gone into the subject minutely or only generally?—I have worked it out from a section which I have sent in to the Commission.

4377. What is the quality of the water?—I cannot speak to that, but I know that the water there is very bright and very clear from my recollection of it, I have explored all those valleys.

4378. Is it hard water or soft water?—It is not very hard water, and it cannot be, because it is caught as soon almost as it falls from the clouds to the surface, and it does not pass through the rocks.

4379. But you get some of the water from the rivers, do you not?—I get it all from the rivers, but it is caught so soon almost as it falls by taking it at the head of those streams.

4380. However, you are not prepared to speak to the quality of the water?—No.

4381. What is the character of the country at the head of those streams whence you intend to take the water?—It is a wild country.

4382. Is there any agriculture there?—Sheep-feeding on the hills is all I know of.

4383. What is the geological formation of the country?—It is the carboniferous system all through; in some places the limestone, and in some places the millstone grit. It is altogether a carboniferous series of rocks.

4384. In the course of the route between this place and London, do you go through any mining district?—Yes; the line would pass through Ashby-de-la-Zouch, which is a mining district.

4385. Would not the water be polluted thereby?—No, not at all, because the channels would pass over, and could not have any communication with the mineral district.

4386. You mean that it would be in closed pipes?—Yes.

4387. Are there any mines at the head of those rivers whence you take your supply?—I do not know of any, but there may be. I cannot speak to that.

4388. But would not that fact have a bearing upon the question of whether the water was pure and wholesome or not?—No doubt it would, but I cannot imagine that it can be very much contaminated, knowing that that is a beautiful district for fishing, and where there is good trout and grayling, generally speaking, you find the water very pure. Cotton says that the river Dove is the finest river in England for trout and grayling.

4389. But you are aware that when Cotton wrote there were not so many manufactures about?—No, there were not.

4390. Cotton wrote as far back as 1759, and there have been a good many changes in the face of the country since that time?—There may have been mines opened certainly.

4391. When was the last time you were in this district at the head of this river?—It is 20 years ago, but I examined it then so minutely, that many things are quite as fresh upon my mind now as they were at that time.

4392. Although 20 years ago there were no mines opened and no manufactures up there, they might have been opened since, but you are not aware of them?—I am not aware of them, but I believe that most of the mines are lower down. At the time that I speak of I examined, I dare say, more or less, 1,000 miles of country to ascertain the best line for a railway from London to Manchester, and that led me up the Dove to its head through Buxton, and that way, and also up the Derwent from Derby to its head; and almost all the streams I personally examined. Indeed I may say I walked up the greater part of them, so that I am familiar with the district in consequence of that.

4393. Does your scheme embrace the notion of supplying any of the towns on the route between Mill Dale and London?—Yes, it would take in a greater population than any other line that could be laid out, because, first of all, going from London, it takes in Barnet, Luton, Bedford, Wellingborough, Kettering, Market Harborough, Leicester, Burton-upon-Trent, and Uttoxeter, and from Uttoxeter there are not many towns until you get to Buxton.

4394. To supply those towns which you have mentioned you would want more than 100,000,000 gallons, would you not?—Yes; of course my estimate has only reference to London; but if the towns on the way are to be taken into consideration, then, of course, the pipes would have to be larger, but a much larger quantity of water could be got than I think of bringing to London. I only bring one-fifth part of the rainfall, as I said before.

4395. What do you allow for compensation to keep up the rivers and for evaporation, and so on?—They have too much water, and I should say they would be glad to get rid of it, because all the low valleys up to Uttoxeter and Doveridge, Tutbury, and those places, are often inundated, and they would rather be without the water.

4396. They would rather not be inundated, but supposing at times when there was no question of inundation, but in times of drought, would not your scheme drain the river altogether?—No because I would have reservoirs up above to take the water during heavy rains.

4397. You take 48 inches as the average rainfall, and one-fifth of that 48 inches you take to be 100,000,000 gallons for London?—Yes; the remainder would go into the present streams as at present which eventually fall out into the Humber.

4398. You mean that you would take the surplus water in fact?—Yes, I would take the surplus water.

4399. Do you apprehend that you would not reduce the rivers at all?—It would reduce them at floods; but then I say it would be a benefit rather than otherwise.

4400. If you reduced them at floods, would you not also reduce them at other times, and would not the same operation which reduced them at floods reduce them at average times?—It would not be absolutely necessary, because by having storage reservoirs above Mill Dale, which might be the case, we could supply water to the rivers so as to equalize the flow.

4401. When you say "which might be the case" you mean that that would be part of your scheme?—Yes.

4402. Do you mean that you would fill the reservoirs at flood times and not get water from the rivers at ordinary times?—Not when there was a very great scarcity; but generally with moderate rains I think it might be spared up in that district without injury to any one of the streams.

4403. You take a quantity of water at flood times and fill the reservoirs, but in ordinary times would you also take the water?—I would when it could be spared; but water cannot be obtained anywhere without taking it from some existing purpose to which it is applied. Therefore, that would apply to every plan. I mean that if you take water for one purpose you cannot have it for another purpose. But I think, that by taking the water from that district it would do less injury than in any other district, because taking the river Humber, the Trent runs down to the Humber; but there are no very great ports upon the Humber above Hull, and therefore it would do no injury, but in the case of the Thames, if you take the water away from the Thames you are doing an injury to the port by abstracting the scouring power.

4404. From your recollection of the ground between Mill Dale and London should you say that the works would be heavy?—Not particularly heavy, nothing impracticable or impossible.

4405. We know that no civil engineer ever yet admitted that anything was impossible, and there is a scheme now as you are aware for making a railway to France underneath the channel?—Yes, and I happen to be the proposer of it.

4406. Generally speaking, from one end of this scheme to the other are the works heavy in an engineering point of view?—Not at all.

4407. Looking at the section, there appears to be a great quantity of tunnelling?—The line laid down upon that section referred to the railway which I mentioned, but the line for the works which I propose for the water is upon the section which I sent in to the Commission and I have merely shown you the larger section to show the section upon which I base the plan that I sent in.

4408. This section which I hold in my hand, the larger section, is a copy of a section which you drew

G. Remington, Esq.

5 June 1867.

for the purpose of making the railway from London to Manchester?—Yes.

4409. With the usual gradients I suppose?—Yes. The railway line is shown by the red line, but the water lines as far as that section goes are laid down in blue lines.

4410. But it would appear that there is a considerable amount of tunnelling?—Yes, there would be a good bit of tunnelling, but tunnelling for such a purpose I consider would not be expensive.

4411. Just before you get to the 114th mile the red line seems to cut the top of a hill; then it seems to go with a slight decline for a considerable distance, but over the tops of the hills and valleys too?—Yes, it would partly be on embankment and partly through pipes on piers. I should put the pipes over the valleys on piers.

4412. This section before me does not show that?—No, but the section which I sent in is more detailed than that, if you will refer to it.

4413. What average fall do you get per mile all the way?—If it was one uniform fall it would be 2·12 feet per mile.

4414. Is that fall enough to carry it all that distance?—Yes, plenty; it would come at half of that.

4415. Are there any valleys that you go down and up by syphon?—Yes, several.

4416. Would the 2·12 feet per mile enable you to do that?—Yes, but at those points, in some places, the inclination would be more.

4417. You mean that 2·12 feet would be the average?—Yes, that would be the average, taking it right through.

4418. That would be the greatest fall?—I dare say in some places it would be double that. Supposing there is a syphon pipe starting from this high reservoir at Battle Flat, and going down the valley and up to the next ridge upon the opposite side, it would be as the difference of those two levels of the reservoirs.

4419. (*Mr. Prestwich.*) Have you any map of the district?—I have the Ordnance map of the whole district from London to Derbyshire.

4420. Does it show the position of the reservoirs?—Generally it does. I have not marked the places, but I could point out the general position of them.

4421. You have several reservoirs which you propose to construct?—Yes, I propose to have one upon each of the ridges separating the valleys.

4422. Do you go as far as the High Peak?—I catch the water from the High Peak; but it would be conveyed from a point lower down, at Mill Dale which is lower than the High Peak.

4423. And also, do you take it from the valleys to the west of Bakewell?—Yes, above Bakewell from Monsal Dale on the Wye and Calver on the Derwent.

4424. Those valleys are all upon the millstone grit, are they not?—Yes, a great part of them are on the Derwent.

4425. Whereas the valleys of the Dove are on the limestone?—Yes, partly, and there is some millstone grit there.

4426. Therefore the waters probably would be of a mixed character; some of them would be soft and others hard?—Yes, they would be of a mixed character no doubt. I consider that the water of the Dove is brighter than the Derwent generally.

4427. You made the observation that owing to the rapid flow of the rain off from the hills the character of the ground would not probably much affect it, but have you any reason to suppose that that would be the case?—The inclinations of the hills are so rapid that the water has not time to percolate much through the surface of the soil before it is down in the valleys.

4428. But whenever it falls upon a calcarious surface, it always immediately takes up a certain quantity of carbonate of lime, does it not?—In some cases that might be so.

4429. Have you any reason to know that it would be otherwise?—No.

4430. It is on the opposite flanks of those hills that the Sheffield and Holdfast reservoirs are fixed, is it not?—Yes, it is upon the same mountainous range of hills.

4431. Therefore the water in that range would be of a very similar character?—Yes, very similar. I might observe that the town of Bristol is supplied from a district similar in its geological character to what I propose at the Dove, that is to say, in the new works that were carried out by Mr. Simpson some years ago at Bristol from the Mendip Hills. The water from the Mendip Hills falls upon the same description of limestone.

4432. From your experience should you have any preference for either hard or soft water in the supply of towns for general purposes?—My own opinion is, generally speaking, that water the purer it can be got and the more directly from rain without impregnation the better. When I was at Bermuda I carried out a great number of tanks, the whole of the water there is rain water.

4433. That is a matter of necessity at Bermuda, is it not?—It is a matter of necessity; the water is stored in tanks holding about 3,000 tons some of them, and the water keeps as pure as possible in those tanks, and it is so soft that the people never think of boiling it for washiug clothes, and I believe it is, generally speaking, liked by all naval men visiting Bermuda for watering the ships and so on.

4434. You have taken out of a supposed rainfall of 48 inches about 8 inches of the quantity of which you would avail yourself for the supply of London. Is there any reason why you limit yourself to so small a proportion as that?—Not at all, I only took that as the basis of my estimate, because I considered that about 83,000,000 gallons per day was the quantity supplied to London by the existing companies, and I found that that would take about one-sixth part of the rainfall upon the hills of Derbyshire above Mill Dale.

4435. Supposing you are right in your estimate, what quantity do you consider that you might safely reckon upon out of the rainfall of 48 inches?—I do not see why we might not take at least one-half if it was required.

4436. You are probably aware that it has been stated to us in evidence that it is hardly safe to calculate upon the average rainfall, but that you must take rather the minimum quantity in any one year?—It is safe to do so, but I have made provision for that in the size of my reservoirs. There is never a month I should say passes in this district without rain.

4437. You have not made any gaugings yourself, but are there not gauges at Buxton and Bakewell and in several parts of Derbyshire?—I cannot find any record of them, but there may be.

4438. What is the nearest town where you have any record of the rainfall?—At Uttoxeter, which is down below considerably. Generally speaking, I consider that the higher you go the more rain you get.

4439. Then you think that the quantity that you now reckon upon might be doubled?—Yes, we might take double with safety.

4440. But also you reckon, do you not, that various large towns might be supplied?—I do.

4441. Supposing London were to require a supply of 200,000,000 gallons a day, you would hardly have any to spare for the other towns according to your estimate?—Not without taking more; not without taking water from the rivers, but that is not likely to occur for many years; but there is the river Churnet also, from which a deal of water might be drawn by extending a branch aqueduct up above Alton as stated in the paper I sent in to the Commission, that would give an additional area of collecting ground of about 70 square miles, and add greatly to the supply.

4442. Do you know whether many of those towns in the district through which your line passes require an improved supply of water, for example, Derby, Burton-on-Trent, and Stafford?—I have no doubt they do, but I have not been there recently so that I cannot speak positively.

ARTHUR SYDNEY ORMSBY, Esq., examined.

A. S. Ormsby, Esq.

5 June 1867.

4443. (*Chairman.*) You are a civil engineer?—Yes.

4444. Will you inform the Commissioners what societies you are connected with?—I am a member of the Institution of Civil Engineers, of the Royal Irish Academy, and an honorary member of the Academy of Sciences at Philadelphia.

4445. You have published a pamphlet, have you not, upon the water supply of towns?—Yes.

4446. And also with regard to the supply of water to troops in India and in the colonies?—Yes.

4447. You have, therefore, devoted a considerable amount of attention to the subject?—I have.

4448. Are you connected with any of the water companies?—No.

4449. Have you been engaged in laying out any waterworks in any part of the country?—Drainage works I have, but not specially waterworks. It is a branch of civil engineering, and as such I have attended specially to it.

4450. I mean you have not carried water from any part to any towns either in this country or Ireland or America?—No; but I beg leave to remark that experience of works may be attained by observation as well as by actual charge of them. I have seen and carefully examined all the principal waterworks of America, India, and Australia, as well as the other countries I have visited in the pursuit of professional information and experience, and I think I can say, without boasting, that I have seen and examined more works of the kind than any other engineer now living.

4451. Are you prepared with any scheme to bring water to London?—I am.

4452. What is your scheme for bringing water to London?—I propose to give a limited supply only for drinking and cooking, and to economise the other sources of supply to such an extent as to meet the requirements of the population.

4453. How do you propose to economise the water?—By devoting it to the special purposes for which it is sought.

4454. That is to say for drinking purposes?—No, the present supply I assume to be solely calculated for common use; for washing, for animals drinking, for steam engines, manufactories, &c., and that class of purposes. I submit a memorandum showing the consumption of water at present, from which it will be seen that the three West End districts are the largest consumers of water:—

From the "Times," May 29th, 1867.

The Registrar General has to acknowledge the courtesy of the London Water Companies, who have furnished him with the average daily quantity of water supplied for the month of April 1867; thus, according to their account, 94,103,007 gallons, or 427,553 cubic metres of water, equal to about as many tuns by measure, tons by weight, were supplied daily; or 975 litres, rather less than a ton by weight, to each house, and 139 litres (=30·5 gallons) to each person.

Companies.	Number of Houses supplied in		Average Daily Supply of Water in Gallons during the Month of

South Essex* - -	978	986	189,023	184,023

NOTE.—The water includes the supply for manufactures and for various purposes other than domestic consumption. In April 1867 the total number of houses supplied was 438,389; average daily supply of water, 94,103,007 gallons. This return, as compared with that for the previous month, shows an increase of 1,298 ouses and an increase of 1,978,099 gallons of water supplied daily.

* The secretary to the South Essex Waterworks Company, writing in October 1866, said:—"We have not extended our mains at present west of Romford." In other words,—not to London.

ANALYSIS of the above Return, showing the Quantity of Water consumed per House in the Districts supplied by each Water Company in April 1867.

	Number of Houses.	Gallons per House.
Grand Junction - -	26,918	334
Chelsea - - -	26,821	279
West Middlesex - -	36,515	237

East London - - -	91,975	202
New River - - -	113,208	186
Southwark and Vauxhall -	70,997	186
South Essex - - -	986	186

4455. Do you mean that the existing water companies should supply water for those purposes and for those purposes only?—Yes, for those purposes alone.

4456. What is your proposal with regard to water for drinking and cooking?—I propose to obtain that from rain water upon a principle which I believe I have discovered myself, that is to say, the non-absorbing principle. I propose to cover over a certain area, as is shown in sketch 6 in the pamphlet which I have handed in, with an impenetrable surface, and to collect the water from the surface into reservoirs.

4457. The space of ground which you represent by the dotted line on the plan is supposed to represent how much?—That depends upon the number of inches of rainfall, and the number of population to supply.

4458. We are now dealing with the supply of London, with a population of 3,000,000; having that in view what do you intend this to be?—I put down the daily consumption at 3,000,000 gallons, and the evaporation and waste, at say 10 per cent, 300,000 gallons, making the total daily consumption 3,300,000 gallons, and this at 6·25 imperial gallons per cubic foot would be equal to 528,000 or say 530,000 cubic feet, which divided by 8 gives 66,250 cubic feet or the quantity required at each station in order to give one gallon per head per diem, and this amount must be collected, stored, and distributed at each station. In order to provide for contingencies I assume that there will be 90 days supply required at each station. The rainfall in that time or three months may be taken at six inches, or 135,744 gallons per acre, and as 3,300,000 multiplied by 365 gives 297,000,000 gallons or the total quantity required per annum, then 135,744 divided into 297,000,000 would give 2,188, which is the area in acres of the entire collecting surface, and this divided by 8 gives 274 acres as the area of the collecting surface at each station.

4459. You state that you enclose the piece of ground represented by the dotted line. My question is what size is the piece of ground which you so enclose?—2,188 acres, or less than $3\frac{1}{2}$ square miles.

4459*a*. Will you explain further this drawing?—I propose to cover the surface either as shown in sketch 5 with a roof of glass and iron and wood, or with a prepared surface as is shown in sketch 6, or by a combination of both as is shown in sketch 7. The rain falling upon that surface passes off from the inclined portions into the tube which is shown by the dotted line, and passes down through an opening into a pipe connecting with the reservoir itself.

4460. What is the size of the reservoir?—If one reservoir were made it would be 35 acres, but if separate ones were made they would be 5 acres each.

4461. What do you propose to do to supply London with water for drinking and cooking purposes?—I propose to have eight collecting grounds of 274 acres each in different directions around London, or to have one collecting ground of 2,188 acres at one place, whichever may be considered most advisable in an economical point of view.

4462. (*Sir J. Thwaites.*) What would be the yield from the 2,188 acres?—It would be equivalent to 1 gallon per head per diem for a population of 3,000,000 persons.

A. S. Ormsby, Esq.

5 June 1867.

4463. One gallon per head is not sufficient, is it?—It would be sufficient for drinking and cooking purposes.

4464. (*Chairman.*) You would, of course, keep the two supplies separate?—Yes, quite separate.

4465. Do you think that that would be practicable?—Yes, quite practicable.

4466. Take a London house; you propose that one part of the water supplied should be for drinking and cooking?—Yes.

4466*a*. And another part for waterclosets?—No, the water that is supplied for common use is at present supplied for waterclosets, and there is no necessity for altering that arrangement further than to prevent waste; but the additional supply which I propose is for drinking and cooking, which would be supplied within the house, while that supplied at present would be, as it is at present, outside the house.

4467. Would yours be a constant supply?—Yes, and it would be equivalent to the number of persons in the house. For instance, if there were five persons in the house, the landlord or the occupier would arrange with the water company to supply a gallon per head for five persons, and he would receive that by meter, according to the plan which is adopted at Rouen and other places.

4468. Will you explain your plan further; after collecting the water in those tanks, how do you get it to the house?—By pipes from the district reservoir.

4469. And you propose, do you not, to have eight around London?—Eight collecting grounds or one complete collecting ground.

4470. Where would you propose to have that one complete collecting ground?—On Salisbury Plain or some other equally suitable place. It is impossible to give the exact localities without making proper surveys, the expense of which is too considerable to incur on speculation only.

4471. Then we are to understand you to say that you have not made any calculation as to what the cost would be of supplying London with drinking water from Salisbury Plain, taking one gallon per head per diem for a population of 3,000,000?—No, I have not; at least, not one that would be at all suitable to lay before the Commission. I could not do it; it would be simply misleading. I have made a rough estimate, which may be some guide, and nothing more.

4472. What is your rough estimate?—4,800,000*l*.

4473. What is the height of the reservoir at Salisbury Plain above Ordnance datum?—It is about 280 feet, as near as I could get it.

4474. And what height do you propose to be when you get to London?—Not having the necessary levels and surveys I have not gone into that question, but there is no difficulty about doing so, because of the very considerable height it is above London. I can suit it, in fact, to anything that is required, but as water is not required at a high level for drinking and cooking purposes, I simply propose to take it at as low a level as economy may suggest in the construction of the works.

4475. When you say that you do not require a high level, how would you give it to the houses?—By pipes from the distributing reservoir, in the same way that the present pipes are laid, until subways are constructed to receive the pipes.

4476. Would you not require pumping?—The present supply does, but the future supply for drinking and cooking purposes would not have any pumping. Being collected at such a level, it would be delivered by gravitation to the basements of the various houses in and around London.

4477. You think that a collecting ground 280 feet above datum would be high enough?—With regard to Salisbury Plain, I have not been able to get the exact levels, but they are from 300 to 400 feet, and I believe that a collecting ground at that height would be sufficiently high to enable the water to be delivered to the basements of the houses in London.

4478. I understood you to say 280 feet, now you say 400 feet?—The collecting ground varies there; I have a statement of the actual height, and it varies considerably.

4479. (*Mr. Harrison.*) What is the minimum height?—The minimum height is 280 feet.

4480. (*Chairman.*) What is the rainfall in that district?—The average rainfall during 10 years is 28·69 inches.

4481. Is it regularly gauged?—Yes; the returns from various authorities are given, and the names of those who have made observations on the rainfall around the Plain.

4482. (*Mr. Harrison.*) What is the minimum rainfall?—25 inches.

4483. (*Chairman.*) When you have collected this water, what would be the gradient of the watercourse between Salisbury Plain and London?—Really I have not gone into that question; but it is one that can be easily regulated.

4484. It is an important fact, is it not, to discover how you get the water to London from Salisbury Plain?—Of course it is a very important fact. It is a fact connected with the complete design, the surveys, the levels, and so forth that are necessary to be made in order to make the estimate for the works; but it is sufficient for my purpose, I venture to say, to prove that it can be done.

4485. Is not it an element in the case as to whether it can or cannot be done, to know what the fall of the water would be?—Of course it is.

4486. And that you say you have not determined?—I have not got the levels and I have not got the surveys.

4487. Might it not result in your finding that you could not bring water from there to London?—No, not at all.

4488. Why so?—Regulating valves can always be put to prevent too great a velocity; besides, the distance is 84 miles.

4489. But supposing there is not fall enough, what would you say?—There is fall enough; 200 feet in 84 miles is quite sufficient.

4490. What gradient will that give you?—It is a quite sufficient gradient for any point in London.

4491. (*Mr. Harrison.*) You assume, do you not, that when you get it to London you will have to pump it again?—No, as it is unnecessary to supply it at any point in London higher than that at which it could be delivered by gravitation, which is all that is needful for drinking and cooking purposes.

4492. (*Chairman.*) Have you not an approximate estimate of what the scheme would cost?—Yes, I have. I assume that the cost of forming a collecting ground, similar to sketch 6, would be 1,200*l*. an acre.

The witness delivered in the following estimate:

ROUGH ESTIMATE.—One acre of collecting surface.—See sketch No. 6 in pamphlet on Water Supply by me.

	£	s.	d.
Land	60	0	0
Earthwork 820 c. y. at 6*d*.	20	10	0
Concrete in cement 810 c. y. at 9*s*.	364	10	0
Slates squared and set in cement 4,840 square yards at 2*s*. 6*d*.	605	0	0
Gutter 55 yards at 10*s*.	27	10	0
Brick enclosing wall 63 c. y. at 25*s*.	78	15	0
	£1,156	5	0

Or say 1,200*l*. as the assumed cost of collecting surface per acre; then

	£
Constructing collecting surface of 274 acres at 1200*l*.	328,800
Reservoirs say	30,000
Piping and other distributing works	150,000
Extra work, say	50,880
Surveying, &c. &c.	40,320
Cost of one station	£600,000
	8
Probable cost of 8 stations	£4,800,000

4493. How do you propose to carry this scheme out; that is to say, who are to make the reservoirs?—I propose that a public company should be formed precisely

similar to the other water companies, so that London would possess, instead of eight water companies, nine, similarly constituted in every way, with only this addition, that the accounts should be more strictly looked after to prevent the possibility of those difficulties which have already occurred in connexion with public companies.

4494. Do you propose a more accurate audit?—Yes, there should be a Government auditor at each board, or a Government director, somewhat similar to the Indian railways, so that no expenditure should be incurred without the knowledge of the Government. I am not an advocate for Government interference, but the dreadful amount of fraud in the management of limited companies renders it most desirable that some check should be put upon it.

4495. What sort of country would you have to come through; is it an easy or a difficult country?—I propose to go along the railway, and to make arrangements with the company to lay pipes along the side of the line.

4496. But how could you do that?—By negotiation with them. I should say that there would be no difficulty.

4497. Surely a railway company would not be enabled to make any such arrangement under the powers of their Act?—Then I should lay the pipes so that they would not injure the railway; I would generally take the line of the railway as near as may be, provided it was found suitable; but it is impossible to state the exact line without a survey.

4498. A railway company is incorporated for certain purposes, and they have power to levy tolls under the provisions of their Act. They clearly would not have the power to enter into negociations to lay down pipes for water?—Not unless they received that power from the Legislature. Supposing in the Act of the proposed company powers were taken to negotiate and to admit of pipes being laid, if found suitable, upon the ground of the railway company, it could be done. There is always a certain amount of surplus ground connected with every line.

4499. Would that be possible?—Yes. I am unable to give any statement with regard to the actual location of the works, and only a general idea of the construction of non-absorbing surfaces for collecting and storing water, for the simple reason that no surveys have been made, and that without the most detailed surveys any estimate that I could give would only be misleading the Commission.

4500. Supposing it were practicable to get the water to London, you say that you would deliver it there in the same manner as the other companies do?—Yes.

4501. And you would have another rate?—Yes.

4502. So that in point of fact there would be two water rates?—Yes, there would, but the pure water rate would be small compared with that for fresh water.

4503. What number of gallons per day do you calculate upon supplying?—3,300,000 gallons per day.

4504. Taking the population of London at 3,000,000, you propose to give a gallon per head per day?—Yes.

4505. Then you would propose, would you, to take away from the existing water companies the right of giving 3,000,000 gallons per day?—Yes, or I would increase their power by giving them an additional 3,000,000 gallons a day. The reason as I understand of the present inquiry is that the water companies are not able to supply the requisite amount of a sufficiently pure description.

4506. That is the subject which we are investigating, and we have not yet arrived at that conclusion, but you state that there would be, according to your scheme, nine water companies in lieu of eight?—Yes.

4507. And the ninth water company would take power to give to the inhabitants of the metropolis 3,000,000 gallons a day?—Yes.

4508. That being water which would be exclusively used for cooking and drinking purposes?—Yes.

4509. The other eight existing water companies would therefore not have the power of supplying the 3,000,000 that would be used for cooking and drinking purposes?—Certainly not.

4510. But if they say that they can do it, how are you to compensate them for taking away from them the profit that they make out of the 3,000,000 gallons a day, which you propose to give to the ninth company?—I do not see any necessity for compensating them, because of the simple fact of their not being able to supply the class of water that is required for drinking and cooking.

4511. But you are aware that their argument is that they can?—But we have the most eminent testimony to show that they cannot. We have the analyses of the different waters to show that they are absolutely supplying poisonous water, and that they are not able to supply water of such purity as is suitable for drinking and cooking.

4512. You by your scheme say to the eight existing companies, You shall not under any circumstances supply a particle of water for drinking or cooking?—Yes.

4513. Upon what principle would you say that?—Upon the principle that the water companies are not able to supply pure water at present.

4514. That is the point which they dispute?—But then when it is proved not only theoretically but practically, that they are not able to do so, they have no right to complain.

4515. In point of fact your scheme is based upon the fact, or rather I should say upon the assumption, that the existing water companies cannot and do not supply water for drinking or cooking that is fit for those uses?—It is, but I would rather take the word "fact" than the word "assumption." If you believe in analytical chemistry, you must say it is a fact, but if you deny its existence as an exact science, then you may take it as an assumption.

4516. Then take it as an assumption. I say that your scheme is based upon the assumption that none of the water companies can or do supply pure water to the metropolis?—As a matter of course it is.

4517. What do you consider to be water that is unfit for drinking or cooking?—Anything but rain water.

4518. Why do you come to that conclusion?—From practical observation in different parts of the world that there is considerably less mortality where rain water is used than where other water is used, and that where bad water is consumed the mortality is especially great; besides this, it is contrary to common sense to admit that rivers, which are the open sewers of the country, can give pure water, no matter how much it may be filtered, and I appeal to medical and chemical evidence in support of this view of the case.

4519. But do you mean that all water except that which is rain water is bad?—For purposes of health I do, that is to say, for drinking and cooking.

4520. Have you any figures to show us what effect the water supplied by any of the water companies in London has had upon the population?—The Registrar General's returns, showing that a very large mortality exists in the districts supplied with the East London Company's water, and with the other water that are taken at a point where the Thames is considerably polluted. I refer to those in support of that view.

4521. In the case of the other companies whose water is not taken where the Thames is polluted, is there a very high rate of mortality in their districts?—I have not remarked it.

4522. Is not that a feature in the case, because you state that all the water supplied to London is bad?—For the purposes of drinking and cooking it is.

4523. That is, so far as health is concerned?—Yes.

4524. But would London as a whole, excluding the East London, district, show that there is great mortality consequent upon the supply of water?—I do not condemn all the water of London upon the ground of the great mortality from it, but I do condemn it upon the

A. S. Ormsby, Esq.

5 June 1867.

separate analyses of the water supplied by each different company.

4525. Can you give us an analysis of the water of any one company not the East London. Take the New River, for instance?—This is a chemical point, and I refer to Professor Parkes's hygiene, in which he describes the composition of water. In fact, I may say that your Grace's question would be best met by the opinion expressed in his work. I condemn the water supplied from all rivers and from all sources except rain, in which I am supported by the opinion of Professor Parkes.

4526. What is the character of the water supplied to London by the New River Company?—I have not got with me the last analysis of that water.

4527. Or can you state the mortality in the district so supplied?—No, I did not bring the return with me. I did not suppose that the question would have been put to me.

4528. It is a very important feature in the case, is it not?—Yes, of course it is, but I submit that the question belongs more to the medical man than the engineer; the doctor states the disease and its effects with a suggestion as to its cause, the analytical chemist confirms the doctor's view, says that water is the cause of the disease, and they both say to the engineer, we want water, limited in quantity but unlimited in purity, while the ratepayers say, let us have it as cheap as you can.

4529. What is the character of the rain water which you would supply to London?—Pure.

4530. What is the composition of it chemically?—The chemical composition of all rainwaters differs very slightly.

4531. I want to know what the character of the rain water would be when you deliver it in London; how would it be chemically described?—I do not see any other way to describe it than as pure water; rain water is pure.

4532. What do you call pure water?—Rain water, and Dr. Arthur Hassall says, when asked, "You "would regard rain water as one of the purest waters? "Yes, as the purest of all water except distilled; and "I would observe that the quantity of organic matter "contained in the water of the two butts submitted "to examination, bore no comparison to that present "in river water, being at least a hundredfold less." Professor Way says, "I have before stated my belief "that rain water collected in a pure atmosphere, and "on surfaces uncontaminated with decaying animal "or vegetable matter, or with soot, &c., is the most "perfect form of water. It is in fact the nearest "approach to distilled water; but having the advan-"tage over artificially distilled water of being well "aërated, and therefore agreeable to drink. I consider "the water of Farnham, of which we are speaking, to "be rain water."

4533. What do you call the water supplied by the companies?—I call it river water, because it has come in contact with the earth, and therefore has received certain impurities.

4534. What is the character of the water supplied by say the New River Company?—That is river water.

4535. What is it composed of?—I have not with me the last analysis, but I can supply it; I would, however, call it simply fresh water. As a general reply to your Grace's questions on this point, I beg to refer to the important evidence contained in the Appendix (No. 111) to the Report on the supply of water to London, published in 1850, by the authority of the Board of Health. I did not study that Report until some time after I had published my pamphlet on water supply.

4536. Is it hard or soft?—It varies; the chemical composition of the water varies at different seasons of the year; in fact on different days it varies and almost at different hours.

4537. You probably have not gone into that question?—I have not, as it is a question for the analytical chemist who can speak with an authority that no engineer can attempt with propriety. The simple facts are that the London water is impure, and as it appeared to me that rain water was perfectly pure that was all that was required.

4538. The London water you state is impure, but how do you prove it to be so?—I refer to the Registrar General's reports in support of that view. I also refer to the inquiry made with reference to the East London water by Captain Tyler.

4539. Here is the analysis of the metropolitan waters in the Registrar General's report. "The above quantity "of water supplied by the Chelsea company had been "after its descent to the earth as rain contaminated "with sewage or manure matter equivalent to 2,195 lbs. "of average filtered London sewage; but by gradual "oxydation partly in the pores of the soil and partly "in the Thames or its tributaries, and partly in the "reservoirs, filters, and conduits of the Chelsea com-"pany, this sewage contamination had been converted "into comparatively innocuous inorganic compounds "before its delivery to the consumers"?—Dr. Odling states, and Dr. Letheby agrees with him, that it is impossible to deprive water of its impurity when once that impurity has been contracted. In fact I have taken the opinion of those eminent chemists as establishing beyond doubt the necessity for a perfectly pure supply of water for drinking and cooking for the metropolis.

4540. We may take it generally, I suppose, that yours is a scheme which you have not been able to go into with any degree of accuracy in consequence of the large expense that would attend it?—Yes. It would cost about 20,000*l.* to make the necessary surveys which I would have made similar to that of others, but I did not think it wise to lay such imperfect documents before your Commission.

4541. But your scheme is based generally upon the assumption that the eight companies are to be told that they are not to give any water for drinking or cooking?—Decidedly.

4542. And that upon the ground or upon the assumption that none of the water which they do give or can give is fit for either drinking or cooking?—Yes.

4543. And that its impurity leads to great mortality?—Yes, combined with other causes.

4544. Is the average mortality of London very high as compared with other places?—No, but I attribute that to the fact of the population being scattered over a very large area, and that one area compensates for the other.

4545. They all I suppose drink water in some form?—Yes.

4546. If the water is so bad would it not have an effect upon the mortality of the population though they may be spread over a large surface?—It would and it does. For instance, the mortality in the eastern districts is much greater than in the western.

4547. But are not the people in the eastern districts very much overcrowded, and are not the houses very small and dirty?—It is true that that is the case.

4548. Would not it be likely to be the fact that if the water which is now supplied to London is so bad and so injurious to health the mortality in London would be great?—Perhaps it might.

4549. But at the same time you say that the mortality in London is not great?—Not as an average, but in a particular case it is.

4550. Taking London as a whole they all have the water supplied by the water companies, and if the water is bad the whole of London consumes, and mortality is caused by drinking bad, would it not follow that the mortality would be great?—Yes, but then there are other causes for the mortality of cities than bad water.

4551. But you say that the mortality of London is not great?—As an average it is not great; it was 19 per 1,000 for the week ending May 27th 1867. In other cities it varies from 20 to 35 per 1,000, and it was 33 per 1,000 in Glasgow the same week that it was 19 in London, notwithstanding that the former city is supplied from Loch Katrine with what is supposed to be the purest water under the sun. The public rate of mortality then would appear not to be an evidence of the purity or otherwise of the water.

4552. Then do you think that the mortality of London is not a test of whether the water is bad or not?—I don't think it is; not as a general principle. I look upon it that the water is positively bad analytically. It is not fit for drinking, and therefore it should not be supplied for that purpose.

4553. Still people do drink it, and yet the mortality of London is not great?—That is a difficulty which I cannot elucidate. I have looked at it in various points of view, and unless it be from increased temperature in some places above others, the predominance of noxious manufactures, and the increase of those employed in trades which are admitted to be injurious to the human health, I cannot discover a solution of it, but I can say this: there is the analysis of water made by the most eminent men, and there are the opinions of Dr. Parkes, one of the most able writers on the subject, and he says that pure water is rain water.

4554. You mean that rain water is the only pure water?—Yes. I find on referring to the reports on the mortality of the British army that where rain water is supplied the mortality is considerably less than where any other description of water is supplied.

4555. Will you tell us where that is given?—It is given in the table at page 23 of my pamphlet. At column 2 it will be perceived that the death rate at Gibraltar is 5·68, and at Malta it is 6·53. Those two places are in the same hemisphere, and those two places, according to column 6, are supplied with rain. Referring to the Mauritius, the death rate in column 2 is 11·74; that is supplied, as appears by column 6, with rain and well water, rain water principally. The mortality there is very much lower than either in Ceylon or in India, all of them being in the same hemisphere.

4556. But do you mean to put the climate of the Mauritius on a par with the climate of India?—It is very little better. I have been there and I assure you I would just as soon live in India.

4557. There are a great many considerations that come into the comparison, are there not; for instance, where the troops have come from, what state they are in when they get there, and so on; all these are points to be considered are they not?—Yes, of course they are; but the general practical view of the case is that where rain water is used there is very much less mortality than where well water or river water is used, or in fact where any other supply is obtained. Take the case of troops on board ship for example; perhaps you will allow me to refer to a remarkable instance, given by Dr. Parkes, referring to three vessels which left Algiers with soldiers on board. He says, at page 56, "The case of the Argo, recorded by Boudin, is an "extremely strong one. In 1834, 800 soldiers in good "health embarked in three vessels to pass from Bona, "in Algiers, to Marseilles. They all arrived at "Marseilles the same day. In two vessels there were "680 men without a single sick man, in the third "vessel, the Argo, there had been 120 men; thirteen "died during the short passage (time not given), and "of the 107 survivors no less than 98 were disem-"barked with all forms of paludal fevers, and as "Boudin himself saw the men there was no doubt of "the diagnosis. The crew of the Argo had not a "single sick man. All the soldiers had been exposed "to the same influence of atmosphere before embark-"ation. The crew and the soldiers of the Argo were "exposed to the same atmospheric condition during "that voyage; the influence of air seems therefore "excluded. There is no notice of the food, but the "production of malarious fever from food has never "been suggested. The water was however different; "in the two healthy ships the water was good. The "soldiers on board the Argo had been supplied with "water from a marsh, which had a disagreeable taste "and odour; the crew of the Argo had pure water." That I look upon as one of the strongest facts in proof of the assertion that impure water produces cholera. I might, however, refer to many statements that have been made to me by medical men, the most remarkable of which I have from a surgeon-major R.A., who accompanied General Havelock when cholera produced such ravages amongst the troops. My own experience in the Punjab confirms this in the most conclusive manner.

A. S. Ormsby, Esq.

5 June 1867.

4558. There is no doubt that good water is much better than bad, but taking your scheme generally, for that is the only way in which we can deal with it, you think it practicable to have a non-absorbing collecting surface, and you would bring water from Salisbury Plain to London?—Yes, or from eight collecting grounds around London of a smaller area.

4559. You would confine the use of that water for drinking and cooking purposes, and you would preclude the eight existing water companies from supplying any water to London for either cooking or drinking?—Yes.

4560. And your scheme you think would have to be carried out by a public company?—Yes, so as not to interfere with the present companies. I am, however, convinced that all municipal questions—water, light, education, &c.—ought to be under one Board of Commissioners, two of whom should be appointed and paid by the Crown, and the third to be elected and paid by the ratepayers. This opinion is the result of observing the practical working of elected boards in America, Australia, &c. I regret extremely that I cannot give more particular details of the application of my plan to any particular locality, but, as I before said, either the work should be done perfectly, so as to have actual facts to work from, or it must not be done at all.

The witness withdrew.

James Simpson, Esq., examined.

J. Simpson, Esq.

4561. (*Chairman.*) You are a civil engineer and have been in practice for upwards of 40 years?—I have.

4562. Are you president of the Institution of Civil Engineers?—Yes, I have passed the president's chair.

4563. Are you the engineer to the Chelsea and Lambeth Waterworks?—Yes.

4564. And to the Bristol, Cardiff, Cambridge, Aberdeen, and several other works?—Yes.

4565. Therefore your experience I suppose we may say is second to none in this country?—I have had a great deal of experience in water engineering, in fact I have devoted my lifetime to it.

4566. Were you engaged in the New Water Supply to Aberdeen, I mean the works that were open last autumn?—Yes, I designed the works and carried them out.

4567. You are, of course, acquainted with the valley of the Thames, I suppose?—Yes, I am.

4568. Can you state what is the area of the watershed of the Thames?—It exceeds 2,500,000 acres.

4569. Have you gauged the water of the Thames at Kingston?—Yes, I have.

4570. What is the smallest quantity in the driest season that you have found there?—The smallest quantity was in 1864, 380,000,000 gallons per day, after the companies had taken about 50,000,000 per diem.

4571. And that from inquiries on the spot you found to be the driest season that had been known for many years?—Yes, personally I knew that it was a very dry season, but I made inquiries and I found that it had been the driest season of any one known. I made a point of going to all the fishermen and boatmen and all the oldest inhabitants, and I found that it was the lowest water they had known.

4572. What is your belief as to the possible supply to London from the Thames basin?—The supply might be taken from it up to a certain quantity, and then it might be supplemented by reservoirs to double that amount. In fact my own opinion is that from the valley of the Thames we may depend upon 200,000,000 gallons per diem.

J. Simpson, Esq.

5 June 1867.

4573. That is excluding what would be produced by the river Lea?—Yes.

4574. Would the 200,000,000 gallons per day which you say the Thames will afford to London be after arrangements had been made for making new reservoirs?—Yes. There is plenty at present to supply the companies. There is no necessity for reservoirs now, there is a very large supply of water indeed.

4575. In fact your opinion is that the Thames basin is capable of supplying to London by proper arrangements 200,000,000 gallons per day?—Yes, it certainly is.

4576. And that is exclusive of what would be supplied to another part of London by the river Lea?—Yes.

4577. What would be the amount that you would consider necessary to supply (distinguishing between the Thames and the Lea) the population of London which now is 3,000,000?—The quantity last year supplied by the different companies was 46,494,224 gallons daily from the Thames and from the Lea valley 42,253,905 gallons.

4578. Then in point of fact during the past year the supply to London, including the Thames and the Lea, was about 100,000,000?—Not quite 100,000,000 gallons; 88,748,129 gallons is the exact quantity.

4579. And you think that by proper arrangements the Thames alone could supply 200,000,000 gallons daily?—Yes; we have a very large quantity of water passing down the Thames in cases of flood. We have instances of that river rising 11 feet 10 inches above the summer level when a very large quantity of water went down, in fact, it could not be measured at that time. There is very little doubt that it increased 50 fold from the dry weather yield, perhaps more.

4580. Is there a great deal of spring water in the district of the Thames?—A great deal. All the upper sources of the Thames yield a great deal of water from the chalk and from the oolitic strata.

4581. What is the quality of that water?—It is a very good water.

4582. Can you chemically describe it?—It is not very soft water, but is about 12 to 15 degrees of hardness, and when boiled it comes down to three or four. It is a water that keeps very well; you may store it in reservoirs without any difficulty.

4583. Have you tested by Clark's process that the Thames water in its natural state being from 12 to 15 degrees of hardness, when boiled comes down to from three to four degrees?—Yes.

4584. Does it lose all that by the process of boiling?—It does.

4585. Is that an ascertained and known fact?—Yes, it has been frequently tried by chemists.

4586. Is it a fact that the water companies now contribute towards the conservancy of the Thames for the purpose of having their supply protected from being fouled by sewage?—Yes. In the first instance they paid a certain sum, four of them 300*l.* a year each, and one of them 200*l.* a year and 1,000*l.* premium, that was on the removal of their works from the tideway. Last year they came to an arrangement that they were to increase the contribution to 1,000*l.* a year each, making it in fact 6,400*l.*, the conservators undertaking to keep the river in a proper state, and to prevent sewage flowing into it.

4587. You state that there is sufficient capacity in the Thames to supply in fact four times what it does now by certain arrangements being made, would it in your opinion be advisable or practicable, supposing it were found necessary, in order to supply London with a larger quantity of water that large reservoirs should be made at the head of the supply, or on the higher grounds, that the various companies to be benefited by the increased supply of water which they would derive, should contribute to the formation of such reservoirs?—Yes; I would not take it out of the hands of the Thames Conservancy. I think it is now settled down into a very good commission, and that they will take care of the river as a public river, because it is connected not only with the lands adjoining throughout the course of the stream, but it is also a navigation which to some extent has lost its trade, from neglect, but I believe they will recover a considerable portion of it, which would, of course, go to keep the stream in a proper state.

4588. Assuming that it were necessary that one or more reservoirs should be made,—they must be made and paid for by somebody,—from your great experience would you think it right and practicable that those companies should contribute towards the construction of such reservoirs?—So far as they are benefited they certainly should contribute.

4589. *Pro rata*, according to the quantity of water they would receive, will of course have to be determined the proportion which they would have to contribute?—Yes.

4590. But you think that the execution and the maintaining and upholding of such reservoirs should be in the hands of the conservators of the Thames?—Yes.

4591. But the company should be empowered to bear part of the expense?—Yes, as they take part of the benefit they ought to bear their part of the expense.

4592. You see no difficulty in such an arrangement?—No, it is rather a Parliamentary difficulty; it is a question of dealing with a public river which I hold ought not to go out of the public hands, and of course it would require an Act of Parliament, and then the arrangements might be made. At present the Thames is in a very improved state as regards its administration compared to what it used to be, for it has passed into other hands and they are now considering what they can do with it.

4593. My question merely assumed that it would be necessary to make reservoirs, and that those would be the parties from whom the money to make them would come?—Precisely so.

4594. Is it the fact that the existing companies have under their various Acts power to take double the amount of water that they do at present?—Yes, they have each power to take 20,000,000 gallons per diem.

4595. But they do only take 10,000,000 gallons?—Yes, they take 10,000,000 gallons each daily on the average.

4596. So that until that power was exhausted it would not be a question of reservoirs?—No, and even after that I think it is a question whether reservoirs would be wanted for very many years. We may go 14 or 15 years without that extreme low water which would render it necessary.

4597. What is the state of the supply of water to the metropolis now as compared with what it was some 10 or 15 years ago?—It is about double I should say in quantity.

4598. Has it improved in quality?—Very much indeed, there is much less organic matter, and it is altogether a different state of things.

4599. Have the water companies who have got those large powers laid out any money in the improvement of their works?—Yes, very large sums of money; one of the companies that I am connected with has laid out 400,000*l.* and the other 300,000*l.* This paper, which I will hand in, contains the quantities supplied by those works.

The witness delivered in the following table:

LAMBETH WATERWORKS.

RETURN of QUANTITY of WATER supplied, NUMBER of HOUSES, and POPULATION.

Gross average *daily* quantity	8,950,000 gallons.
Quantity for other than house supply per day	1,251,000 ,,
Quantity for house supply per day	7,699,000 ,,
Number of houses	37,203
Quantity for each house per day	207 gallons.
Population	225,000
Quantity per head of population	34·22 gallons.

NOTE:—The Company supply about 5,000 houses in the country districts which take large quantities of water for gardens, small fountains, &c.

5th June 1867.

CHELSEA WATERWORKS.

RETURN of QUANTITY of WATER supplied, NUMBER of HOUSES, and POPULATION.

Gross average daily quantity - -	8,000,000 gallons.
Quantity for other than house supply per day - - - -	1,193,000 ,,
Quantity for house supply per day -	*6,807,000 ,,
Number of houses - - - -	26,900
Quantity per each house per day -	253 gallons.
Population - - - -	201,000
Quantity per head of population -	33·86 gallons.

* House supply includes stables, and about one-fourth of the houses are of the largest class.

5th June 1867.

J. Simpson, Esq.

5 June 1867.

4600. You state that the question of the quantity of water is undoubted, and that they have the power of supplying London with a great deal more than it wants is a matter beyond all question?—Precisely so. Allow me to say that the Thames is one of the finest rivers in England, and as a matter of experience I never would go to a small river if I could get water from a larger one, where the drainage ground is so good as it is in this case, and we know that it comes down in a very pure state for a very large portion of the year. It is only in excessive floods that we get any colouring at all in the water.

4601. As to the question of the supply, which you say very confidently is ample (and no doubt a gentleman of your experience and position would not state it unless he was quite satisfied of the truth of what he asserted), will you state to the Commission what grounds you have in coming to that conclusion?—From knowing the district intimately, and having been employed on it professionally for many years, and in fact I have watched the question of the flow of water in the Thames beyond what a private individual would do, I have gauged it professionally, and I have had some opportunities of observations which most persons would not have.

4602. During the last 10 or 11 years have you had constant gaugings made?—I have had a register of the water taken since 1852 every morning at 9 o'clock, so that I know the state of the river, and I have also during the last 40 years advised the Crown respecting their waterworks at Windsor Castle, which obtains its water from the Thames, and is worked by a water-wheel. I have also been consulted by many millowners on the river from time to time.

4603. Then it is a fact that since the year 1852 you have had daily gaugings taken of the Thames?—I have, with reference to the summer level, every morning at 9 or 10 o'clock.

4604. Have you it in any tabulated form that you could let us have so as to append it to the evidence?—Yes. It has been published in the report of the evidence given before the Rivers Commission.

4605. (*Sir J. Thwaites.*) You made a section of the river, did you not, above the point where you take the supply?—I did. The fact is, that many persons point to Teddington Lock as the measure of the water, but you cannot gauge it at Teddington Lock. The body of the weir is not tight, and many persons say there is no water going through when it ceases to go over the weir; but a large body goes long before it ceases there. My gaugings were taken from observations of the stream itself. I have selected a parallel part of the river; the sections are extremely good, and I depend upon them. I know that they are accurate, because I attended to them myself.

4606. Has the condition of the river where you took the section altered at all since you took it first?—No.

4607. Have you taken those daily gaugings for 11 years?—Yes.

4608. Have you a register in your office of the quantity flowing over?—Yes, I have.

4609. Can you mention the smallest quantity passing over?—The smallest gauge that I took was 380,000,000 gallons after the water companies had taken 50,000,000.

4610. Were not the gaugings taken above your point of supply?—Just above the point of supply; but there was an allowance made for the quantity that two of the companies took; the other three companies were below it. The usual flow of the Thames there in dry seasons is about from 600,000,000 to 700,000,000 gallons, it is very seldom below that; and within the last 12 months it has been about from 900,000,000 gallons to 1,000,000,000 gallons, and sometimes more than that.

4611. But taking what you would call an ordinary dry year it is about 600,000,000 to 700,000,000 gallons?—Yes.

4612. (*Chairman.*) You have heard, have you not, of the various projects that have been started for bringing water to London from various parts of the country?—Yes I have.

4613. Mr. Bateman has a scheme for bringing the water from Wales, and Mr. Hemans and Mr. Hassard have a scheme for bringing it from Cumberland; what is your opinion of Mr. Bateman's scheme, or have you looked into it sufficiently to express an opinion upon it?—I have not paid very great attention to it although I know the country extremely well and have frequently been over it. I think it is an interference with the river Severn which is of very great importance in that part of the country, and with the lower reaches of the Severn which are so liable to be affected by sandbanks; and considering the great trade and the sums of money that have been spent upon that river it seems a very questionable scheme to me whether it should be interfered with, because you would be taking from that river the very life of it. You would be taking the water that scours the stream in the most essential times you would at all events take the crest of the floods if you took no more. I think it would require a very attentive survey. It is a subject which I myself am not ignorant of, because I was engaged with Sir William Cubitt in the arrangements for the introduction of locks and weirs on the Severn. I was there for some years and I know that he was extremely anxious not to have the floods interfered with; he would rather pass them off, and the weirs were made of a very wide character with the view of passing the water quickly.

4614. (*Col. Harness.*) Which is the particular part of the Severn which would be first affected do you think?—There is navigation above, but Stourport above Worcester would be the first place.

4615. (*Sir J. Thwaites.*) Would the tendency be for the river to silt up at the mouth if the water were abstracted?—Yes, the sand banks and shoals of the Severn now are very liable to shift, and it would be a very serious injury to the trade on that river if anything were to occur to it to cause any further obstruction.

4616. Do you think that the abstraction of the flood water would have a tendency to cause the river at this moment to silt up?—I think it would, it is a matter about which I should be extremely jealous.

4617. (*Chairman.*) If your proposition is tenable, namely, that there is ample water in the Thames to supply London, and that that water is good, then there would in your opinion be no necessity for going either to Wales or Cumberland?—I think not. I think the project is open to other objections. I should doubt the possibility of bringing a large watercourse of that kind across the country, say 180 or 200 miles. We know that there is great difficulty with canals in this country. Of my own knowledge I know that in hard frost of 1813–14 the Chelsea Company on the failure of the New River supply, pumped water into the New River mains at Charing Cross, and a snow storm came on in the afternoon, and the river was practically stopped. You cannot contemplate anything with an open watercourse of that length of 200 miles.

4618. That would go rather to prove, would it not, that you would object to subjecting a population of 3,000,000 to one source of supply for water?—Yes, and it would go further than that. I believe there is a

J Simpson, Esq.

5 June 1867.

notion that it would be brought in to gravitate to the whole metropolis. Now that I do not believe, for so far as I have studied the matter, Stanmore, the place where they talk of constructing reservoirs, would be only 200 feet above the Thames, whereas in the case of the New River they must be supplying places at Hampstead 400 feet, and the Lambeth Company have cisterns 400 feet above the Thames.

4619. (*Mr. Harrison.*) Those are exceptional cases I presume?—No, not exceptional cases. They are increasing in magnitude every year; all the Crystal Palace land is upwards of 355 feet above the Thames.

4620. (*Chairman.*) The objection as to silting up at the mouth of the Severn, of course, would not apply to the Cumberland and Westmoreland scheme, but they are at a great distance from London, and of course your objection as to distance would apply to that scheme in a greater degree?—As regards the conveyance of water to London it certainly would. The Bala lake water was proposed for Liverpool, and at one time it was thought that they would convey it there, but it would have affected vested interests very seriously. The Ellesmere canal receives a very large portion of its supply from the Dee, and I question whether in dry seasons without making very large reservoirs they would be able to carry it through. I do not think they could supply the Ellesmere canal and the town of Liverpool as well, but a detail survey is certainly necessary before any proper conclusion could be arrived at in respect of that source.

4621. You know that it is alleged (and it is for this Commission to get information upon that point) that the water supplied to London is insufficient in quantity and excessively bad in quality. Would you subscribe to that doctrine?—No, I certainly do not subscribe to that because I know that so far as the companies that I am connected with are concerned it is quite otherwise. They are only too anxious to give a proper supply. But the difficulty which they experience has been with regard to the owners of small property. There is an immense difficulty in dealing with the supply of the poorer neighbourhoods and one which I confess they have never been able to surmount. Some years ago I took great pains on behalf of the Chelsea Company who were taunted with the want of supply to the inhabitants of Westminster, to lay down pipes from the mains and have water constantly on. Immediately that was done the middle men sold all the cisterns and leaden pipes, and in the next year they refused to pay the money. They said that their tenants had not the water and that they had a right to the water, and in the course of seven years the whole of that work was destroyed which cost the company 800*l.*

4622. Do you think that the constant service is a desirable thing?—It would be a very difficult thing to apply unless the companies have more power, in fact it must become a question of police, otherwise I do not see how it can be applied. We have the greatest difficulty with those small properties. It is nobody's interest to preserve the fittings, at least nobody does interfere. It is a part of the pastime of the children to injure them, and the least thing that would fetch a penny they will steal. The stealing of anything in the nature of metal goes on constantly, so much so that they even have a little crowbar to enable them to draw the nails and sell them.

4623. The quantity of water you have told us is ample, and might be doubled or quadrupled; and with regard to the quality of the water which is alleged to be had, you state that it is from 12 to 15 degrees of hardness?—Yes, it varies according to the season.

4624. What is the operation of that upon the health of the drinking consumer as compared with the use of soft water?—I can give no direct comparison. I know that it has been alleged that there is very great economy by the use of soft water for washing, and other purposes, and they say it saves the wear and tear of clothes, but I think a great deal of that is speculation. I confess, however, that I have not gone into that question.

4625. With regard to the effect of the London water, which your companies supply, upon the health of the population, do you consider it an unwholesome water?—No, decidedly not. I have drunk it myself all my life—in fact it is a water which I prefer, and the chemists have gone very particularly into that point for the companies. Dr. Letheby has analysed it in the most minute way, and I believe the water to be as wholesome as any water that we can obtain.

4626. Are you aware that it is said that the attack of cholera was owing to the badness of the water supplied to the east of London?—I have heard so, but I have heard also that the same water was supplied to another district, where there was no attack at all. At the time of the cholera I paid very great attention to it, in fact I had all the district which we supply attended to, especially at Chelsea, and I confess I did not quite believe all the cholera reports. There was a great deal stated then which we did not find to be true, and a great deal in idea. Dr. McLean, who was at that time attached to that part of the district, stated places where the cholera was likely to happen, but not a single case occurred. I took great interest in it at the time in Lambeth, to see what was the state of the case. It was alleged then that in the same street, in houses supplied with water by the Lambeth company, there was no cholera, whereas in the houses supplied by the Southwark company there was. At that time the Lambeth company had removed to their present source, and had in fact improved their supply; but I question whether what was stated with regard to that street had any foundation, because it was at the end of a competition with the neighbouring company, and we really did not know which houses were supplied by the one or the other. During the change and excitement of the competition many houses got on to our works that we did not know of. At the same time there is no question that when you can get good and wholesome water it is much better than any tainted water for the supply of the population.

4627. Are we to understand that you have heard nothing or seen any returns that would lead you to believe that the water supplied to London is bad in quality and injurious to health?—I certainly have not. I believe that a great deal of what has been stated upon that point is merely assertion without inquiry. I have been in the habit of being consulted by towns not only in England but on the Continent, and I doubt whether any city in Europe is better supplied than the metropolis either in quantity or quality. In London we have water supplied to ordinary houses on every floor, and we have not only cold water but we have hot water. We have the closet system carried to a greater extent than in any town that I know of, and the convenience of the water supply in London, and the intricacies of it, are greater than one could possibly imagine. In fact when the late Mr. Thomas Cubitt was constructing all those houses in Belgravia I was at his elbow in supplying his houses with water, and he made a merit of it that he would supply the houses in an improved way; and in consequence of that, there is no doubt, he let them and sold them to an immense extent.

4628. Am I indebted to you for the supply of water which I enjoy in Belgrave Square?—Yes, and I believe in that district we can say what some towns in Europe cannot say, that we go through the week supplying something like upwards of 27,000 houses, with only two or three complaints, and many of those arise out of people's own fault. Practically all those houses have a constant supply, for the cisterns which carry them through from day to day are supplied every day in the week, Sunday included.

4629. (*Sir B. Phillips.*) Are they supplied by the Chelsea Company?—Yes.

4630. (*Chairman.*) Would it come under your knowledge if disease were produced by water supplied by your company?—It would.

4631. Would complaints come to your company?—They would. It is a thing which the directors of the company have been extremely anxious about, and in all cases of apprehension or application to them by any authorities special attention and immediate attention is paid to the matter. We do not wait for boards or anything, even the turncock is ordered to turn on the water in case of necessity and to report and not to wait for orders at all.

4632. I understand you to say that during the attack of cholera last summer the subject received your own especial and particular attention in some district in which your company were interested?—Yes it did.

4633. And you made minute inquiries?—Yes.

4634. And could you discover that any attack of cholera was the result of your supply of water being bad?—No, I could not. At the same time it might have been, but the fact is, the habits of the poor are so exceedingly filthy that you do not know how to deal with them. Even where they have a daily supply of water the receptacles are so bad that you cannot keep the water from hour to hour in anything like a proper state.

4635. What you mean is, that it would be hard to attribute to the water the existence of disease in any poor and destitute neighbourhood as being alone the cause?—Yes.

4636. But the badness of the houses, the badness of the ventilation, and the filthy habits of the inhabitants should be taken into consideration also?—Yes, and more especially the bad drainage, because, although the drainage is very much advanced in the metropolis, the lateral drainage or the minor drainage has still a great deal more to be done to it, there are many very filthy places.

4637. Would there be any means of filtering the water if a further supply were wanted before it was brought into the pipes to carry it to London from the upper grounds?—Yes.

4638. Have you had any experience in the provisions of the Act which was passed within the last few years for compelling towns to utilize their own sewage?—It is a subject which I have watched and a most difficult subject it is.

4639. Do you think that steps might be taken with regard to the water from the head of the Thames if a larger quantity were required to ensure its being as pure a quality as it is now?—By an Act of Parliament of this session the Thames Conservancy are under obligation to the water companies to exclude sewage from the river, and not to permit the towns to drain into it, and there is no reason why they should do so. Of course they plead the expense, and no doubt it will be an expensive thing to do, because the land round many towns near London is becoming very expensive, but still in the case of Croydon they have recently purchased land to the extent of 35,000*l.* with the view of securing permanently the means of disposing of their sewage by throwing it over the land, and I do not see why other towns should not do the same. It is a question no doubt of making it profitable, and I do not think that that difficulty is quite solved at present. At Croydon they sell a great quantity of Italian rye grass which they grow on land improved by the sewage of the town, and to some extent I believe they have made a profit of it, but still I do not think that we are in a condition to apply that experiment to every town. At Croydon they are near a large population with a ready means of sale for this rye grass which they would not have in small towns. Again, in many towns the sewage manure would come into competition with stable manure which everybody would prefer for gardens.

4640. (*Sir J. Thwaites.*) Rightly you state, do you not, that double the quantity of water might be taken from the Thames than is now taken by the companies without any injury whatever being done to the river?—I believe that to be so.

4641. That would give something like 100,000,000 gallons per diem?—Yes, it would.

4642. You also stated, did you not, that even beyond that quantity water might be taken without making any special provision for storing the storm water?—Yes.

4643. Could you say to what extent the principle of abstraction might be carried without injury to the river?—It would be difficult for me to say that at present, because I do not know what the effect of the improvement of the stream will be. At present in the upper part of the stream, and all above Staines, the weirs and locks are in such a state that the water runs off directly; there is no impounding at all.

4644. But they are repairing those weirs, are they not?—They are repairing the weirs, but till we know the effect of them, it will be difficult to say positively, but I should think from 120,000,000 to 130,000,000 gallons, more might be taken without affecting the river, and without making reservoirs.

4645. 120,000,000 gallons might, you think, be taken without injury to the river?—Yes, or 130,000,000.

4646. But you believe that provision by means of reservoirs might be made so as to give at least 200,000,000 gallons per diem without difficulty?—I believe so.

4647. How many years do you think it would be before the metropolis would require a supply of 200,000,000 gallons a day?—It is difficult to conceive that we can ever arrive at that point. My mind is principally directed to the distributary pipes. Here have we been at work more than 50 years, and some companies have been at work 70 or 80 years, and we only now distribute 50,000,000 gallons. It would always be limited by the distributary pipes, but we seem to be increasing now at the rate of about doubling every 40 years, that is the rate at which we are now going on.

4648. You do not assume that the population doubles in that period, do you?—It has been going on something like that.

4649. But in speaking of the 200,000,000 gallons, assuming that 100,000,000 gallons is now the proper supply for the metropolis, that would assume that the 200,000,000 gallons would only provide for a metropolis of double the present population?—Yes, a metropolis of double the present population and double that again.

4650. I suppose the tendency of substituting water-closets for cesspools in the metropolis has for the last 30 years been going on very rapidly?—Yes, it has, more particularly within the last 15 or 20 years. I believe that in the course of five years something like 80,000 cesspools, or even more than that, were done away with in the metropolis at the instance of the late Board of Health.

4651. Did I rightly understand you to state that 200,000,000 gallons might be taken from the river without any special provision of storage?—Yes.

4652. You spoke of the Act of last session, which enables the Thames Conservancy Board to exercise some control over the towns up the river to Oxford inclusive, so as to prevent the discharge of sewage. I believe that the consideration for the payment of 6,000*l.* on the part of the Conservancy Board was the exclusion of all sewage from the river?—Yes, they undertook to bring in a bill, which they have done this session, and I believe there is no doubt that it will pass, for it has passed the House of Commons, and that will have the effect of giving them the power of shutting out the sewage practically. They will have to give 12 months' notice, and there is a certain machinery which, if worked out by them, will protect the river completely.

4653. Their obligation is not simply to bring in a bill to obtain powers, but to put those powers in force, is it not?—Yes.

4654. And the water companies would have a right to withhold the payment in whole or in part of the 6,000*l.* if the Thames Conservancy Board do not

J. Simpson, Esq.

5 June 1867.

perform their part by causing the sewage to be intercepted and preventing its flowing into the river?—I do not know what power we should have of withholding the money, but I believe morally, if not judicially, the obligation is on the Conservancy Board, and they have undertaken it, and from what I know that they have been doing, I think there is no question that they will carry it out with very good effect.

4655. We understood from Mr. Burstal that they have given notice to the several towns, having regard to those provisions in the Act, the tendency of which is to prevent the river from becoming polluted by the discharge of sewage and other matters, and that would necessarily improve the water very much, would it not?—No doubt it would.

4656. You have observed, no doubt, the condition of the river at different points, and especially at points below where the sewage is discharged; how far down the river from the point of discharge have you been able to trace the presence of sewage?—Lately there has been a great deal of flood water in the river, at least it has been 2 or 3 feet above the summer water level, and I have not been able to trace any. I think the river is in a highly improved state throughout, in fact I know it is.

4657. Especially within the metropolitan area?—It is, beyond all question; in fact, we have quantities of fish going up the river now which we had not before. When I was a boy I know that at Chelsea we used to catch smelt, and I have caught them recently at Kingston again, and that is a very delicate fish.

4658. How long a period elapsed from the time that you last caught smelt to the time of their re-appearance?—I should think 40 years.

4659. Were they formerly in a large number and in a healthy condition?—Yes; we had opportunities then of catching them, and we used to have them two or three times a week at that time.

4660. From what you can recollect of smelts 40 years ago and the smelt which you have recently caught, are they in as good condition now, do you think?—I think so.

4661. Forty years ago there was no sewage flowing into the Thames, was there?—Comparatively not; so much so that we used habitually to bathe from the banks. I have often swam across the river, and rested and come back again, but latterly I should not have done such a thing.

4662. You are probably aware that there was a penalty 40 years ago upon any one discharging sewage into the sewers?—Yes. I believe the late Mr. Saunders, who was the chairman of the Westminster Commissioners, was the principal instrument of getting the waterclosets put in, and I know he told me that the power of the human manure was so great that it dissolved everything, and it was beneficial to have it discharged into the sewers. However, the mischief did not commence exactly there. The trouble in the metropolis was when they turned on so many together into the sewers, because formerly a large number of houses had only cesspools, in fact, up to a recent date they had only cesspools.

4663. Waiving the question as to whether the application of sewage to land may or may not be a profitable speculation, as an engineer and an intelligent observer of the attempt to apply sewage to land, is it your opinion that it can be applied without difficulty to land, and might therefore be taken out of the river? Yes, it is my opinion, and I state it rather beyond that of an engineer. I have been an amateur gardener all my life; when I was at Chelsea I cultivated land and sold the produce. It was an amusement to me, and I at that time used Thames mud very largely in my garden, and I know that whenever I have been able to apply it in a liquid state, I have improved the produce very much indeed. I used to grow remarkably fine cabbages there, and I think that by attention a great deal, if not everything, can be done with it. I confess that I do not go to the extent that some people do in the application of sewage to confined areas, but I say if you have plenty of room to pass it off I believe you may deal with it, but if you are to continue manuring land with it day after day, and month after month, you will not succeed. I happen to have watched the use of it at Croydon, and that is the result of my observation there. I think they are continuing it too long; they will have to allow the land, as the farmers do, to lie fallow for some time. That land, if they dug it over and let it lie fallow 12 months, would be much better afterwards than it is now.

4664. Are they constantly applying the sewage there?—Yes; it must be a larger area, and I think for a town like Croydon 20 or 30 acres is not enough.

4665. Have they not 250 acres to apply to that object?—You will find that the quantity which they apply it to is very small in comparison with what they state.

4666. Did you observe the water running off at Croydon after the sewage had filtered through; I mean the water that passed off into the upper part of the Wandle?—Yes, I have seen it frequently.

4667. It ran off apparently in a pure state, did it not?—Not exactly pure, although to the sight it is pure.

4668. I suppose it was entirely in a liquid state?—Yes; there is no question of that, but when that water has been filtered it has been pronounced sewage after all. Of course it is much more diluted. But Croydon I think is a particular case, because they have the power of dilution there to a very large extent. Some years ago I happened to pay a visit to a place near Mansfield, which takes the sewage of Nottingham; it is the Duke of Portland's property, and a friend of mine, Mr. Farrey, who was the steward of his estate, told me, when walking over the property, that if they smelt the sewage in the morning it was then too strong to put it on the land in cultivating Italian grass. I think if you employ sewage you must dilute it well, and then you may pass the water off, and as the refuse comes off you get water slightly fouled in comparison.

4669. Confining that principle to the towns on the river Thames do you think that the water running off in the condition which you refer to would be objectionable?—I think not, presuming the process is fairly carried out.

4670. There being a large volume of water in the Thames to neutralize it?—Yes. Of course I assume that they arrest all the solid matter.

4671. Having regard to the area of the Thames, 2,500,000 acres, what do you assume to be the rainfall due to that area?—The rainfall towards the lower part is about 25 inches, and in the upper portion the rainfall that we have records of would produce an average of about 30 inches. We know that in Gloucestershire a great quantity more rain falls than is the case in this direction.

4672. What do you think would be the average on the whole of the Thames basin; would it be more than 25 inches?—I should think it would be from 28 to 30 inches.

4673. Have you calculated the 28 inches on the area referred to and compared it with your gaugings above the point where you take your water at Hampton?—No, I have not done that.

4674. Are you able to say how many inches out of the 28 are really available for the water supply?—Taking our usual quantity I should say that about 14 inches would be due to evaporation and absorption, and probably we might allow 4 inches more for other things, which would bring it to about 10 inches available. I have not calculated it but it would come to an enormous quantity of water.

4675. On that large area no doubt it would be so, but when you take your gaugings above the point where you take your water supply you of course get the net result?—That was allowed for in the gauging which I gave you; they were deducted from that and added to the other amount.

4676. But you have not worked out the quantity flowing over the point where you took your section

of the river so as to show how many inches that would be over the whole area?—No.

4677. But from observation you believe that out of 28 inches 10 inches would be available for the water supply?—Yes, I do; that would be in accordance with my observation in other districts. Of late years we have had an opportunity of applying that principle to many towns where the gravitation system has been introduced, and we know a great deal more about it now than we did a few years ago.

4678. You state, do you not, that the water of the Thames is on the average something like from 12 to 15 degrees of hardness?—Yes, according to the season and the quantity of rain in the river.

4679. But that hardness is subject to be reduced by boiling from three to four degrees?—Yes.

4680. Do you calculate that the whole so reduced would be equal to rain water for washing purposes?—Yes, I think so.

4681. And that it is simply a question of the water used for drinking purposes being from 12 to 15 degrees of hardness?—Yes. The quantity of soft water used is very small in comparison with the larger quantity required for a town. The food and drinking water we cannot of course separate from the total quantity supplied, but I doubt whether it is 5 gallons per individual *per diem*, where 25 gallons is the quantity supplied.

4682. A great many persons have no means of storing rain water, and, therefore, it passes off?—Yes, rain water is in such a state that you cannot do anything with it. I know, living out of town, I have occasionally taken houses where there is no water laid on, and the receptacles for receiving the rain water are very sooty and very filthy. I was consulted for the supply of Calais, and that was essentially a rain-water supply, and one of the most filthy things I ever investigated, and there is no doubt a good deal of disease occurred from that cause. I know that kidney diseases are very prevalent in districts where they use rain water, more especially where coal is burnt.

4683. Do you mean that it is the carbon or the nitre in the water that is deleterious?—The nitre principally, I believe, it is which acts upon the kidneys.

4684. Of course, after the testimony which you have borne, you are of opinion that there is ample capacity in the Thames watershed to yield a sufficient quantity of water for the supply of the metropolis independent of any other source?—I am certain of it.

4685. And that the water as a whole is good water?—Yes, and I am not quite certain whether I might not go to the extent of saying that it is superior to what you get from Wales, and superior to that which is supplied to the northern towns, because the water in many of them is very peaty at certain seasons. The Severn water at certain seasons is as brown as coffee, and it is not a pleasant water to drink, and if you go into Manchester you will find that they use coloured tumblers to contain drinking water, and that their object is really nothing more nor less than to conceal the colour. I know when water was introduced into Liverpool from Rivington Pike, there was a great complaint of the colour of the water. They had been in the habit of receiving the red sandstone water which is quite pellucid and as bright as a diamond; and the inhabitants complained very much about the colour of the water, and it is objectionable there is no doubt.

4686. Entertaining the view which you do as to the means that you have of obtaining an ample supply, and especially connected with the prospective improvements in purifying the river itself, you are of opinion that it is not necessary to go a distance to obtain a supply of water for the metropolis?—I am. I think it would be not only a very difficult thing, but a most expensive thing to do, and when done I question whether you would be as well off as you are now.

4687. But independently of that you have an objection to bringing water so great a distance in open cuttings, inasmuch as being liable to be interfered with by frost and by heavy falls of snow, the supply might be cut off?—Yes, and I think that so large a community ought not to be dependent for its water supply on one spot.

4688. Do you know whether the New River Company have experienced any difficulty in their river during times of hard frost?—I have not of late years heard of it. I believe occasionally they have a great deal of snow falling into their stream, but I happened to know that when a boy I went with my father to the New River in the hard frost of 1813–14, and the river was so far reduced by what I may call jelly ice that the Chelsea company were obliged to pump into their mains at Charing Cross.

4689. Was that on one occasion only?—On one occasion.

4690. Since then there has been no interruption to the flow of water, has there?—No, I believe not; I have not heard of it.

4691. They break the ice, do they not?—Yes, they break the ice. The water is interrupted in its flow very much, no doubt. I should have a very great objection to a long cutting of that kind. You would have a great deal of metal pipe, cutting, and shafts, and a great deal of trouble with it.

4692. You stated that Dr. Letheby had examined the water. Has he been employed professionally to examine the water of your companies?—Yes, he has.

4693. Has he been employed professionally to examine the water of any other company?—Yes, of all the companies. I believe it is the most complete analysis of the kind which has been made.

4694. Has he long been employed in that capacity?—He was employed, I think, last November in conjunction with Dr. Odling and Professor Abel.

4695. Is he paid by your company or by the companies generally?—I believe the professional men will receive the amounts and divide them, but I do not know exactly what the arrangement is. There is a general understanding upon the subject.

4696. He is professionally employed by several companies for the purpose of making those analyses?—Yes.

4697. And he is so employed now?—I think his employment has ceased. He has given evidence before the committee of the House of Commons.

4698. You, I think, are in some doubt as to the application of the principle of constant supply, and you referred to some experiments that you made in Westminster?—Yes.

4699. Do you think that under proper regulations, with ample authority of inspection and control, it would be impossible to apply that system?—There are such difficulties attending it, and I hear of them on all hands, that I think it is not only a large experiment to introduce, but it would require an amount of interference almost greater, I think, than we should carry out in the metropolis. Recently I have heard of the supply at New York having failed through the waste of water, and I have also recently received reports from the city of Boston upon the same subject, from which I have taken some extracts which will show the difficulties that they have had to contend with there. The New York cases are something of the same sort, but they seem to have gone to an extent of severity almost that we should not admit of.

4700. Did that failure of supply in Boston occur during the time of the war between the northern and the southern States?—No, it is spread over several years; it goes from 1859 to 1865, and it seems that between January the 1st, 1865, and May 1st, 1866, the number of notices issued for leaks was 9,555, and the number of persons fined for waste was 3,093. They were wasting one-half of the water; then it had this bad effect that the inhabitants of the higher parts of the town could not get any water at all, because the lower parts used it, and they persisted in throwing water over the streets, although they were actually starving in the upper parts of the town.

J. Simpson, Esq.

5 June 1867.

These are notes extracted from the reports of those different years, which I beg leave to hand in.

The witness delivered in the following paper:

MEMORANDA as to the WASTE of WATER under constant Supply at BOSTON, U.S., from 1859 to 1865 inclusive. Extracted from the ANNUAL REPORTS of the WATER BOARD to the CITY COUNCIL.

REPORT FOR YEAR 1859.

Page 31. Daily consumption 13,175,000 gallons against 12,847,000 gallons previous year.

In 1858 consumption 72¼ gallons per head, estimating population at 178,000.

In 1859, if population taken at 183,000, consumption 72 gallons per head, scarcely varying from that of 1857 and 1858.

"It seems as if we might now fairly conclude that the individual consumption had come to its maximum, the variation in three years not exceeding one gallon."

Meters applied more numerously than in previous years, and proposed to be used still more extensively.

Appendix page 4. Waste water from lake over dam into Sudbury river in the year 7,569,000,000 gallons.

REPORT FOR 1860.

Pages 6 and 7. "Consumption of water.—In the last annual report the following language was indulged in: It seems as if we might now fairly conclude that the individual consumption had come to its maximum, the variation in three years not exceeding one gallon, say 72½ to 73 gallons, but the present year is a fearful example of the fallacy of such calculating. By the report of the engineer it appears that the average daily consumption of water has been 17,238,000 gallons. By the census returns it appears that the number of inhabitants is 177,902. This shows a consumption of 97 gallons for each individual, an amount believed to be without parallel in the civilized world. Of course there is nothing in the sales of the water that could lead to the expectation of such a monstrous increase, and we must again resort to the old story of extravagant and inordinate waste."

Lake never full to height of dams during year, so that whole available supply drawn, although rainfall 55½ inches against average of 48¾ inches.

With a rainfall of 55½ inches the maximum yield of this lake will be 17,700,000 gallons, but as average only 48¾ inches a proportional diminished supply can only be safely relied on.

Page 8 Capacity of aqueduct put to severest test that ought to be applied, and to work it under any increased head must be attended with the utmost hazard.

Conclusions:

1st. That the lake cannot be relied on for any greater supply of water.

2nd. That the aqueduct can convey no more water than it has done this year.

"These conclusions are of a nature to arrest public attention and to induce inquiry. What is to be done? What use shall we make of the present quantity, in view of the great difficulty and expense of increase? Every effort

Page 9. should be made to guard against *waste*. . . . When all the unnecessary uses of the water are stopped, then, in case of insufficient quantity, it would become the policy of the city to cut off, one after another, the classes of takers for mechanical purposes. It is to be hoped, however, that the time is not near at hand when this will be necessary; it is only alluded to as indicating what would undoubtedly become the policy of the city at all times, in order to supply a full and needful quantity of pure water for domestic purposes. Meters continued to give satisfaction and would be more extensively used."

REPORT FOR 1861.

Page 9. Dam at outlet of lake raised and further supply from a pond brought into lake.

"With this addition to the source of supply there ought to be water enough for the city without any additional expense, and the Board are confident there would be were it not for the wasteful use of the water in the city. This has been a topic of discussion in the various water reports for several years. The present Board have adopted energetic measures by the aid of the police in preventing this evil, and these measures have been attended with marked success. At the same time the only efficient remedy must be found in the citizens themselves in the use of water, and in giving information of any wasteful use by others, or by the general adoption throughout the of water meters, and an entire change in the assessment and collection of water rates."

Some methods of using water highly objectionable; hopper closets for instance. No water to be supplied to hopper closets made after 1st January 1862. Pa

Most satisfactory method of charging water would be by actual measurement; but practical difficulties against introduction of meters over the whole city, and plan would require expenditure of half a million dollars for meters. Pa

Average daily consumption 18, 189, 300 gallons being 951,000 gallons in excess of previous year. Pa

On the 1st January 1862 water in lake 7 feet 11 inches below high-water mark leaving only 2 feet 1 inch above low-water mark. Pa

As consumption of water increased so fast, and lake supply would very soon be all used, engineer recommended survey to be made to determine a new source. Pa

REPORT FOR 1862.

Average daily consumption 16,600,000 gallons being 1,589,300 less than in 1861. Saving mainly owing to meters being placed in establishments where large quantities of water used. Pa

Surplus water from lake into river during year 33,200,000 gallons equal to about two days' supply. Pa

Quantity used equal to annual average rainfall, and all that lake can be relied on to furnish annually.

More storage room needeed, as well as a new source of supply.

REPORT FOR 1863.

254 meters in action. Their use, where large quantities of water consumed, proved to be very satisfactory; in places where large numbers of hands employed, a great deal of water wasted, but when proprietors obliged to pay for it by the gallon they find it for their interest to do what they can to prevent this waste. Pag

Average daily consumption 16,238,500 gallons. Pag

REPORT FOR 1864.

"Waste of water. This subject, which has been brought to the notice of the City Council in the annual reports of this Board for many years has been and will continue to be a source of great anxiety, and one that will require active measures to prevent. The last two months the lake was at such a low point that the Board believed it to be their imperative duty to use every means in their power to put a stop to the enormous waste which they felt sure was taking, and they commenced by issuing a circular to the citizens, calling their attention to the fact. This had a very good and marked effect, but still a great waste continued, and as the lake was still falling a second notice was issued, and persons having house hose were requested to discontinue its use; and it was also decided to employ a suitable number of persons to examine all the water fixtures throughout the city, and report each day to the office any waste that might be discovered, and also all leaks. This was immediately carried out by the water registrar, and the result has proved that nearly one-half of the water that has been brought into the city has been wasted. For the first ten days, which included about one-third of the city, there were reported 531 cases where water was running to waste, and 1,353 cases where fixtures were out of order and water was leaking on that account. Pag

"We have no doubt whatever but that the supply of water is simple for years to come if used in a liberal and proper manner.

"The active measures which the Board has adopted have already greatly reduced the consumption, or we should say waste of water, and our reservoirs are now nearly full. According to the estimate of the engineer the average amount of water brought into the city daily is 16,681,000 gallons; to bring this enormous quantity we have been obliged to run our conduit to its utmost capacity, and thereby endangering the works; and as we know that a large part of this is wasted, we shall continue to use every means in our power to find out and prevent the same." Page

312 meters in use—Nothing but their great cost prevents their application to all consumers, as the only sure way to prevent a continual waste, as consumers give their fixtures more attention when they are paying for any leakage.

20 men employed by Registrar to examine and report all places were water fixtures out of order and water found running to waste. Page

Daily consumption in November and December about 2,000,000 gallons less than corresponding month last year, owing to increased vigilance and care on the part of citizens inspired by fears of short supply, and by the extra exertions of the Board and it officers in tracing out sources of waste. Page

REPORT FOR 1865.

"Unless we are favoured with copious rains during the summer and fall, it will require the strictest economy to keep up the supply of water throughout the year, without the doubtful and expensive expedient of raising it by artificial means to the level of the conduit. By the tables of the engineer it appears that the rainfall for 1865 was the average of the last ten years. Yet there was during the last year, and is now, a very general complaint in the neighbouring towns of the scarcity of water, and much inconvenience, if not sickness, has been consequent upon it."

"The constant supply with which our inhabitants have been blessed should always be kept in mind, and the efforts of the Water Board *continue* to be seconded by all good citizens, not only by preventing waste upon their own premises, but by giving prompt notice of waste by others. The apprehension of a short supply will necessitate the greatest watchfulness on our part; and if it is found necessary to subject the takers to some slight inconvenience from the visits of the inspectors it must be borne with patience as it is only in this way we can detect the improvident and wasteful."

"The number of notices issued for leaks from January 1st 1865 to May 1st 1866 9,555."

"Number of persons fined for waste - - 3,093."

Hopper closets increased in number to 8,000, and consumption of water found to be many times in excess of ordinary pan closets. These closets, with *improper fixtures*, are one cause of excessive use or waste.

"Board contemplate appointment of two or more officers, whose duty it will be upon an alarm of fire, to assist in opening the hydrants, and to see that they are properly closed after the hosemen have left; to visit the hydrants used for supplying the steamboats with water for cleansing decks and other purposes; and to have a general supervision of all hydrants so far as to prevent improper use. It will be desirable that these officers have police powers. In other cities a large number of such officers are advantageously employed."

Average daily consumption for domestic purposes, found by actual experiment to be $24\frac{2}{10}$ gallons per head.

"The number of meters has been largely increased. If it were not for their high cost (about 50 dollars each) it would be desirable to deliver all the water by measure, and then each taker would pay for what he consumed. If such a system could be adopted, the quantity of water drawn from the lake would be reduced nearly, if not quite, one third."

"However desirable this may be it cannot be accomplished at present, for we have failed as yet to find a cheap reliable meter. The whole number of takers is 27,489, and much the largest proportion pass less than ten dollars a year. Consequently the expense at present cost would nearly consume the income."

Price of water by meter settled at uniform rate of three cents. per 100 gallons = 1*s.* 3*d.* per 1,000 gallons.

Consumption of water for 1865 reduced 25 per cent. as compared with consumption of 1864; one consequence of this economy was that the citizens who resided upon the higher grades were accommodated with a more regular and abundant supply of water than for some years past.

Daily average supply in year, 12,662,000 gallons.

Waste in night: average 282,000 gallons per hour or 6,768,000 gallons per day.

Maximum consumption per day, 18,000,000 gallons.

4701. Are you acquainted with the water supply of Hull?—Yes.

4702. Do you know that they have the constant system in operation there for a large part of the town at all events?—They have, but in the upper parts they overcome the difficulty by having cisterns. I would say that in London I do not believe the difficulty will ever be overcome without cisterns.

4703. The engineer of the Hull Waterworks has given evidence before this Commission to the effect that they have the constant system in operation in a large portion of the town, and that they are adapting the other part of the town to receive the constant pressure, and that the result of the application of that system has been a saving of 25 per cent. in the consumption of water. Would that be in accordance with your views?—I do not think that the one system would involve any more water than the other as far as my experience goes.

4704. Is not the liability to waste the principal objection to the constant system?—It is, but when it can be properly controlled I do not believe there need be any more water wasted under that system than under the intermittent system.

4705. Then what would be the difficulty?—Getting into the houses to stop the waste.

4706. Would not the people of London become used to that kind of control, just as the people of Hull have become accustomed to it?—I do not know, you would experience great difficulty in getting into the houses in London. I have had notice frequently myself of attempts at robbery by persons attempting to get into houses by false personification, and the inhabitants will not allow the turncocks to go into the houses.

4707. (*Sir B. Phillips.*) The better class of houses have in effect a constant supply, have they not?—They have.

4708. Consequently the only difficulty is with reference to the poorer tenements?—Yes, I know it is stated that in many towns the constant supply is carried out, but I do not think we get at all the difficulties connected with it. I will take Cambridge as an instance, they have carried the system out there to a certain extent, and they have succeeded, but they have had very great difficulty. In the case of one of the colleges there were 10,000 gallons wasted, when the quantity required was not 1,000 gallons, and in their Act of Parliament they have got a clause that the water to be supplied need not be constantly laid on under pressure, that is the instance of one town. Folkestone is another, where they used every drop of water out of the reservoir and they were compelled to come to Parliament to get clauses which restricted to four hours in the morning and four hours in the afternoon; and in Bristol also the waste was so great that they came for power to shut off the supply every night, and they have power to do so by a special clause.

4709. You have had great experience of course in the management of all classes of property in supplying them with water. Has any system occurred to your mind which would enable you to give a constant supply to the poor, in a court for example where there are 20 or 30 houses?—One mode which occurred to me was to put up a cistern and allow the inhabitants to have water to draw off constantly, or to put up a sunk tank and put a pump up for them—that would be another way; or another way would be to let the water go direct from the mains and let them draw constantly; but then that must be coupled with some means of compelling them to pay, because when we talk of the poor it is difficult to conceive in this metropolis any poor but those who are really in the workhouse; you must define what poor people are. A great deal of that small property is in the hands of agents, and they would do anything to make a penny or save a penny, and they have very great difficulty in collecting the rents. In the case which I mentioned in Westminster, they would not pay the rent, and they let their tenants go to the adjoining courts for water, and they said that they had a right to the water.

4710. But you have the power to go upon the owner, have you not, to pay for the water?—Yes, but it is a very difficult thing; perhaps he lives in Paris, and you have a difficulty to find out where his agent is, and they play all sorts of tricks.

4711. Cannot you take the house?—No, we have not the power to go to that extent. And in many of those poor houses the chairs and benches are actually chained to the floor.

4712. I suppose the great difficulty really is in substituting something for those filthy receptacles which they have now?—That is so. It is done in the new lodging houses. Miss Burdett Coutts has some houses in Westminster, and the principle of constant supply is carried out in them, and they take about $7\frac{1}{4}$ gallons a day, each individual. To some extent no doubt there is a difference there, because the people are not at home to consume the water all day long, but that is the result of measuring the water into their receptacles, and they have to all intents and

J. Simpson, Esq.

5 June 1867.

purposes a constant supply, for it is on about eight hours a day.

4713. Have they iron tanks to hold it?—Yes, ordinary tanks.

4714. (*Col. Harness.*) How is it measured into those receptacles?—It is measured by a meter which we have introduced of late years on the principle of Barker's mill; by putting centrifugal vanes to counteract the force of the water, we are enabled to measure very accurately within one gallon. It is a very beautiful application, and it is comparatively novel. I believe in Chelsea we have water to the amount of about 7,000*l.* a year sold in that way, and in Lambeth about 5,000*l.*

4715. (*Sir J. Thwaites.*) What is the charge for water per 1,000 gallons?—It is according to a scale, from 6*d.* to 9*d.* and 1*s.*

4716. Does the difference of charge depend upon the quantity?—Yes.

4717. (*Col. Harness.*) I suppose the rotation of the arm is checked by the vane?—Yes, by putting two vanes in and filing them according to the size, that counteracts the centrifugal force, and we are enabled to bring them to measure gallons, but to apply it generally it is an expensive thing; you could not do it for small houses, it can only be applied to a number of houses, otherwise the thing would amount to the cost of the water, and more than that. In the case of the American houses that I have referred to, they would like to apply this principle, but they state that the expense is against them.

4718. (*Mr. Harrison.*) In your experience, what should you consider, looking forward to a few years to come, to be a sufficient provision per head for the population of London, including all public services?—About 30 gallons would be my guide. We used to stop at 20 gallons, but as the inhabitants have got access to water with greater facility, they have increased the use of it; there is no question that the facility of obtaining water increases the use of it.

4719. You do not think it would be necessary in making a calculation to go beyond 30 gallons per head?—That would be quite the very outside for all purposes.

4720. (*Sir J. Thwaites.*) Including manufactories?—Yes.

4721. (*Mr. Harrison.*) Taking it that you can get 200,000,000 gallons from the Thames proper in case of necessity, and say 60,000,000 gallons from the Lea, with the power which they state they could get by additional provision, that at 30 gallons per head would be equivalent to a provision for 8,700,000 people?—Yes, in fact, it would be equivalent to the supply of a number of people which I can hardly imagine ever could be massed together.

4722. Practically, therefore, the Thames might be looked forward to as being able to supply London beyond any possible increase?—I think so.

4723. With regard to the Aberdeen waterworks of which you are the engineer, that would be a soft water, would it not?—Yes, very soft, and there is this difficulty with it, that it acts very powerfully on the pipes, and I apprehend that with all that class of water you would have the same thing occur.

4724. Are the pipes made of lead?—Yes, and iron pipes also. In Aberdeen this action goes to the extent of stopping the pipes up, and they are regularly fouled, but the Aberdeen water is a very beautiful water. Also I may say that that is a peculiar case, because we have no reservoirs for storing the water in Aberdeen. We take it direct from the river and we filter it, and it is delivered into the service reservoir near the town.

4725. (*Sir J. Thwaites.*) That is granite water, is it not?—It can hardly be said to be granite water; the under formation is granite of course, but the water comes from a very large moor district, although we have taken the water from a part above where the moor streams come into the river.

4726. Is there any peaty-colouring matter in it?—A very slight amount.

4727. (*Mr. Harrison.*) Supposing you had within reach of London water similar to the Aberdeen supply, and you had the present Thames water, should you give any decided preference to the one over the other?—No.

4728. You would not look to it as being a great object to obtain a soft water for London?—No, it would be rather a question of expense than otherwise.

4729. Supposing you had them at the same cost, what would you say?—It is a question which is one of choice. But the case of the Aberdeen water does not apply, because there our least flowing stream is about 150,000,000 gallons, and we only want 6,000,000. But there is a very great difficulty, as I would point out to the Commissioners, in obtaining the requisite quantity of water in dry seasons from all those northern districts. The case of the Liverpool waterworks was an actual failure. They went to a place called Rivington Pike, in the direction of Bolton, where there is very good rainfall, but instead of getting 15,000,000 gallons a day, the supply came down to 6,000,000.

4729*a*. Dr. Letheby, in the evidence which he gave before this Commission, stated that if he had a soft water such as you have at Aberdeen at the same distance, and to be attained at the same cost as the present water supplied to London, he should prefer chalk water to soft; do you coincide with him in that opinion?—I do not know that I should not be of the same opinion. I can only say that I have understood recently—I have not seen the French engineer who is in charge of the works at Paris, but I understand they have come to the conclusion to go for water to a district which I know is limestone.

4730. I have no doubt that you, in investigating every matter connected with water, have paid some attention to the reports of the French upon their water supply?—Yes, I have seen them.

4731. Could you give the Commission some facts that may have occurred to your mind in connexion with those reports?—I have seen the reports, and I know that the preference was stated very strongly, after a very long investigation, for waters out of a limestone district. I believe the water is a much better keeping water than it is from the other districts where they could have obtained soft water.

4732. Did they carry their investigation as to the effect of the water upon the men in their army?—I believe they did, and they made out that they had the finest men from the hard water districts.

4733. Do you anticipate a great improvement in the quality of the water of the Thames from the Act of last session?—I do. It is very much improved since the time we went up to our present source. If you remember 15 years ago we were pumping from Waterloo Bridge, and our going to Hampton was a great step in the direction of improving the quality of the water supplied to London. In fact, altogether it is a different system that we are pursuing now. Formerly we never filtered the water, we did not even subside it, but latterly we have been compelled to do it, and not only the water for drinking, but we find that economy is on the side of our filtering the whole of it; we have only one apparatus or system and we can do it as cheaply as we could separate the one supply from the other.

4734. (*Sir J. Thwaites.*) Is yours a sand filter?—Yes. I have tried many experiments in filtering and I have always doubted the propriety of using water that required any other filter.

4735. (*Mr. Harrison.*) Your attention no doubt has been directed to the question of the possibility of separating the water for household purposes from that supplied for other purposes?—Yes, and from personal experience I would rather not have that done. I have had it separated in my own house, that is to say, I refilter the water. The water in my house is brought over the sinks, and it is a continual cause of contention that the water is not bright, and that it has not been drawn from the filtered water cock, so that I am

very sorry that I ever introduced it. One system of water supply in a house is quite enough. In fact, servants will not go to the proper taps at all times; they use that which is nearest to them, although the other may be only a few inches further away.

4736. My question had reference to that which is used for flushing sewers and street purposes, whether it would not be practicable to separate the waters in the case of supply of large towns?—It would be, and I confess it is my idea that it might be carried out in the metropolis, although it is a question whether it is worth while, and there are some circumstances connected with it which should be taken into account at the time when it is considered. In the Chelsea company's district when we were pressed for filtered water we found very great difficulty in supplying a higher service at the time when we were supplying water for the roads, and for flushing the sewers; and we laid down separate pipes, and we have them now, and we do not filter the water for the roads. The only thing against it is the difficulty of keeping the pipes in order, as they would only be used during a portion of the year, practically only during six months of the year.

4737. (*Col. Harness.*) And there would be very few points of delivery?—Yes, and that is what has often struck me when I have heard allusions made to a separate supply for the metropolis in case of fire. How is the service to be kept in order? The only reason in my opinion why our works succeed is that they are constantly in use, and anything happening to them very soon becomes known, whereas if you have part of your system of pipage not in actual use you will find great difficulty in keeping it in order. You will be surprised to hear that with pipes not much used, in the course of a fortnight or three weeks, the purest water at this season of the year becomes quite putrid, and smells dreadfully, and, I believe, that the whole of the pipes, under such circumstances, would be liable to be stopped with black oxide in all the ends of them.

4738. (*Mr. Harrison.*) We have had evidence that it was desirable to supply London with drinking water by a separate service altogether, but that would scarcely be your view of the matter?—If the Londoners would go to the expense of probably a million and a half or two millions of money, or it might cost even more than that, and all the troubles and complications which would be sure to arise, it might be very desirable, but then the question is, whether really pure water is required to an extent beyond which we can get it by filtering it privately. A great deal of what people would call well water is very bad water, even in the country districts, and well water in this metropolis is as bad as it possibly can be, most foul and filthy stuff, and no doubt cholera has been traced to the use of that water. The water immediately below the plastic clay is not a pure water, it absolutely contains double the quantity of organic matter which our river Thames does, and although it is a soft water its softness is due to its containing a large portion of carbonate of soda, which when used for locomotive engines forms an effervescing mixture and renders them liable to explode.

4739. Is there any public officer now attached to the Registrar General's Office who has the power of reporting upon the analyses of the waters of the different water companies?—Dr. Frankland does report upon them. The Registrar General has requested the companies to send him accounts of the quantity of water supplied monthly, and we have done so, but we do not know anything more about it than what appears in the Registrar General's reports.

4740. You are not aware whether there is any public officer whose duty it is to analyse the waters of the companies from time to time, and report upon them?—No more than that Dr. Frankland does report upon them, and I presume that he does communicate with the Registrar General; at all events, we see the analyses in the monthly reports.

4741. If the population increased to double its present amount, the water would be supplied, would it not, in a totally different district from that where it is now supplied?—It would.

4742. Therefore the question of distribution would be only extending the distribution over a larger area?—Yes; a great deal of it would come into districts which are surrounded by houses in the present districts. For instance, there is Chelsea Park, which I suppose contains about 40 acres, with 800 or 1,000 houses, and patches of houses in that way would be in the existing districts, but London is extending in the suburbs to an immense extent.

4743. But you do not anticipate any great physical difficulty in the distribution of the water to all those districts when it is required?—I think we have overcome all that. We have taken it over the Surrey hills to every place where it is required, that is to say, between Kingston, and Norwood, and Croydon, and Beckenham, and London.

4744. Do you think it would be desirable by any Public Act to compel the water companies on the one hand to supply water to the poor, so that they may have a sufficient supply, and on the other hand to compel the owners of poor houses to pay the water companies for that supply?—I think it would be a very good thing to do something in that direction, but I do not quite see how the companies could do it, because there is a difficulty in knowing who the owners of the property are. A man might perhaps have half a dozen houses, and put them in one man's hands to collect the rents and manage the property, and there is very great difficulty in knowing who to go upon to get paid.

4745. Excepting the question of the difficulty of collecting the water rents, you do not see any objection to the principle?—No; at the same time something should be done to compel them to maintain in a proper state the cistern and fittings, and everything that is connected with the supply, for really the great difficulty in the metropolis now is in affording to the poor sufficient receptacles for water, not only in size but in number. They allow too many to resort to the same place, and they have quite a fight for water now.

4746. (*Sir B. Phillips.*) You would have stand-cocks in courts and alleys also?—Yes, only you must have a sufficient number of them; if you get more than 10 houses to a stand-cock, you will find them not sufficient, because the poor people resort to them immediately they come home from their work in the afternoon about 6 or 7 o'clock; that is the principal time when the water is drawn in those districts. There is a difficulty in dealing with that question at present, and that is to induce the persons interested in property to act in any way which involves expense. Unfortunately in some cases the vestrymen are large owners of property and they will not initiate anything, nor will they follow up anything.

4747. (*Mr. Harrison.*) My assumption was that a Public Act might be passed, making it compulsory upon the owners to pay for the supply for the poor people?—That is very good so far as it goes, but we want something more; we want the persons who let their houses to do what once I mentioned in a Committee of the House of Lords, but which was not received with great favour. I said that I would render it illegal to let a house without good drainage and a good supply of water, and that an Act passed in that way would settle the whole question, because then they could not collect the rents at all without complying with the provisions of the Act.

4748. (*Sir J. Thwaites.*) You are probably aware that the principle now adopted with regard to the Reform Bill is to abolish the compounding system, and that the practical effect will be to exclude parties who are now qualified for serving on vestries on their compounded property from those vestries?—I have understood so; I should be very sorry to enter into individual cases, but for the last 40 years I have met with the difficulty time after time, and up to the present moment it is not got rid of. There is one district now with which we are in contention, and I find that it is solely because the parties behind the

J. Simpson, Esq.

5 June 1867.

scenes are interested in the property, and they will not give a penny to improve the supply of water; in fact they are not the right owners at all, to the extent of 50 or 60 houses.

4749. (*Mr. Harrison.*) Do you not know that there is power given to boards of health to close up all houses that are not in a proper state for habitation?—Yes.

4750. Why should not the question of a proper supply of water be equally a question for their decision?—I do not know of anything which should take it out of that category. The fact is the matter wants attending to as much as anything I know, but we have to deal with a class of property to which the owner will not do anything.

4751. (*Mr. Prestwich.*) You spoke of the iron pipes of the Aberdeen water supply getting stopped; how long had they been in use?—I believe about 20 years.

4752. Are you speaking of the new supply or the old supply?—The old supply. The difference between the old and new supply was that one was about 25 miles by the course of the stream down the river where they pumped it, and in the new supply I have taken it at a higher level, so that it does not require pumping. Consequently we have got the water from a purer stream, and we have avoided the moss water locks and streams by going up there.

4753. Have the pipes had to be renewed during that period of 20 years?—In some cases they have been taken up and cleaned out. The manager has been in the habit latterly of coating them with bitumen to prevent the action of the water upon the pipes.

4754. Has that been effectual?—To some extent I believe it has, but I have no faith in it as a constant thing. I think it very likely that the water will make its way underneath the preparation, and then the oxidization will go on as usual.

4755. How long has that coating preparation been under trial?—About ten or twelve years.

4756. In the many towns with the water supply of which you have been connected, Aberdeen and the others which you have mentioned, have you had any cause to see that there was preference to be given to the very soft water of Aberdeen or Glasgow or to the moderately hard water of other towns?—No; apart from their organic impurities, I certainly have not. I know that in many cases where the water has been extremely soft, in the case of Glasgow itself, for instance, they were very apprehensive about the action of the water on the leaden pipes producing carbonate of lead and having the effect in many instances of producing painters colic, of which I have seen cases.

4757. Has the result been such as was feared?—But I believe the real fact of the Glasgow present water is that it contains a slight quantity of sulphate of lime, and however small it may be it is a protection. Many years ago Professor Brande, who was analysing water for me, stated this to be his opinion, and I found it to be the case from practice, that wherever sulphate of lime was present in the water a luting or protective surface formed on the pipes internally, and effectually protected them, and we could use leaden pipes with impunity; but when it was absent from the water, and when free carbonic acid was in the water, we had a difficulty in dealing with the leaden pipes. In the case of the dog kennel at Windsor and of the French royal family at Claremont, there were notorious instances in which the dogs were poisoned by the water. Owing to the water being extremely soft water and containing a certain portion of free carbonic acid, the dogs in the kennel at both places suffered from paralysis of the feet.

4758. The water of Loch Katrine does not show the presence or any trace of sulphate of lime does it?—If there were only a trace of it it would be sufficient.

4759. When you give the quantity of water per head of 34 gallons as being sufficient, that is including all the waste which at present occurs?—That is including everything.

4760. Might not that quantity be reduced providing that the large amount of waste which now takes place could be obviated?—No doubt of it, although the habits of people have very much changed in the last few years, and they use more water generally for all purposes than they did formerly.

4761. The quantity taken from the Thames is at present 50,000,000, but looking to the increase of the population and the future wants of the city, to supply which probably 150,000,000 or 200,000,000 gallons might be required to be taken, will not the question which you have before referred to, of filtering the whole of that water, or only such portions of it as might be required for drinking purposes, become a more important question from year to year to be considered, and whether a large portion of the water for sewers and house purposes might not be supplied apart from the water required for drinking?—That may be so, but you may take this that filtration may be carried on to the extent of 150 gallons per house per diem for 4*s.* 6*d.* per annum, including interest of money and everything, so that it would be a very small sum to save for the purpose of having separate systems of supply.

4762. (*Sir J. Thwaites.*) Do you mean that that is the cost of filtration by the company?—Yes.

4763. Have you any idea, taking the population as a whole, what quantity of water is actually consumed for drinking purposes?—As far as my own observation goes, taking isolated houses, I should think about one fourth is used, say from five to seven gallons per diem for household use, for drinking and for food.

4764. I am speaking now of the quantity used for drinking?—It is a very small quantity, it would be difficult to say how much. I should think that a two-gallon bottle put on the sideboard in the morning would keep the house going the whole day.

4765. (*Mr. Prestwich.*) Are you acquainted with any gaugings of the Severn in the upper part of its course?—No, I am not. There were very elaborate gaugings taken some years ago by the resident engineer to the Commissioners, and sections the whole way down the stream.

4766. Do you find the flow of the Severn more irregular than that of the Thames?—I think it is.

4767. It contains a much larger volume, does it not?—No; a much smaller volume.

4768. Is it your opinion that the quantity of spring water flowing into the Thames maintains a larger uniform flow?—Yes, very much so. The very strata itself has that effect. In the Oxford canal they have a great quantity of water from springs in its bed in the neighbourhood of Cirencester. In point of fact their mode of supplying the canal is the reverse of what is the case with ordinary canals, for instead of having reservoirs above ground they have them under ground.

4769. (*Mr. Harrison.*) I think the Commission have had it in evidence that the summer flow of the Severn at Tewkesbury does not exceed 90,000,000 gallons a day; are you acquainted with that fact?—I daresay it is so; it is very small in comparison with the Thames. I should doubt whether it is even that, and there is an opportunity of measuring it there which there is not in the Thames. I have seen the water very low in the Severn up there.

4770. (*Mr. Prestwich.*) You have no doubt seen the estimate which has been made in Mr. Bateman's pamphlet with regard to the cost of his scheme; have you paid attention to that calculation of Mr. Bateman's?—Yes, I have.

4771. It would appear from calculations that after incurring the expense which would be necessary for carrying out the larger works a domestic rate of 10*d.* in the pound would be sufficient to be levied. At present the rates of the water companies vary from 10*d.* to 1*s.*?—Yes.

4772. If the supply now delivered by the companies were put upon the same footing as that upon which Mr. Bateman and Mr. Hemans based their plans, that is to say if a certain quantity of water be allowed for public use and a compulsory rate or a certain rental valuation of the metropolis, it would

seem to me that the conditions are not upon the same basis; have you ever looked at it in that point of view?—Where the public supply has been introduced in that way, in the case of Manchester, they rate the warehouse property, but we have nothing of the kind in London. I believe that the rate at Manchester is 9*d.* on the house property and 3*d.* on the warehouse property. *J. Simpson, Esq.* 5 June 1867.

4773. (*Sir J. Thwaites.*) But you have a scale operating on the rent?—Yes.

The witness withdrew.

Adjourned to to-morrow at 11 o'clock.

Thursday, 6th June 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Colonel HARNESS.
Alderman Sir BENJAMIN PHILLIPS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

SAMUEL FURNESS HOLMES, Esq., examined.

4774. (*Chairman.*) Are you the borough surveyor of Sheffield?—I am. *S. F. Holmes, Esq.* 6 June 1867.

4775. How long have you held that appointment?—Since the Local Government Act was adopted in the borough, now nearly three years ago, but I held the office of Surveyor to the Board of Highways for important districts in the town for 15 or 16 years previous to that.

4776. Have you adopted the Local Government Act in Sheffield?—We have.

4777. Have you not a corporation at Sheffield?—Yes, we have a mayor and corporation. The town was incorporated in 1843, but they did not take the management of the highways.

4778. But you were incorporated in 1843?—Yes; but we had a Local Act for lighting and cleansing the town, which continued in operation until the adoption of the Local Government Act.

4779. Do you know any other municipality in the country that has adopted the Local Government Act?—Yes, many.

4780. I should have thought that your powers would have been quite sufficient without that?—For the management of the highways they were not.

4781. However you have held the office of surveyor to the municipal authorities under the mayor and corporation under the Health of Towns Act?—Yes, I have.

4782. Since your appointment have you had your attention turned to the subject of the water supply?—We have had our attention particularly turned to it since the unfortunate catastrophe of 1864 when the Dale dyke reservoir burst; since that period the town has watched earnestly the condition of the water supply of Sheffield. Previous to that the water supply had gone on regularly; and we had no cause of complaint. The town has no control over the water or the gas.

4783. What was the source of the supply prior to the bursting of that reservoir?—From storage reservoirs on the watersheds of the rivers Rivelin and Loxley.

4784. And that reservoir which burst was in point of fact one of the receptacles of the water from that gathering area?—Yes.

4785. The new works are not completed are they?—No. The water company's acts have been in existence in Sheffield for a great number of years. I should think for more than half a century, but under the Act obtained in 1853 they obtained further powers, and under the powers of that Act they were constructing the Dale dyke reservoir. It was completed, and they had just filled the reservoir, when on the first night of its being filled it burst and inundated a great portion of the town of Sheffield.

4786. What is the extent of your gathering ground?—The water company have obtained further powers during the present Session of Parliament, the Act for which has received the Royal assent.

4787. Is it a joint stock company which is now supplying water, or is it in the hands of the municipality?—It is in the hands of a joint stock company.

4788. Can you tell us the extent of the gathering ground?—The extent of the gathering ground is about 34½ square miles.

4789. Has it been increased since the accident?—That is the gathering ground which the company have authority to take water from at the present time; it was about 20 square miles; it has been increased since that catastrophe, and is now about 34½ square miles.

4790. Can you tell us the rainfall due to that area?—The average rainfall of 10 years is about 39 inches.

4791. Is that the average of how many gauges?—It is the average of three or four gauges on different parts of the watershed; it is the average of the gauge on the river Rivelin. There is about the same rainfall on that shed as there is over the whole of the 34½ miles.

4792. You say that you have three other gauges?—Yes, there are three other gauges; but there has not been a sufficient number of years yet to get an average that would be a correct average.

4793. How many years have those been down?—I think some three or four years.

4794. What is the result of those three or four years?—I am not in a position to be able to tell that.

4795. Before you have assumed a rainfall of 39 inches, how much do you think, by making allowance for absorbtion and evaporation, would be available for the supply of water?—The amount actually collected in the driest years that have been known of late, that is, the two years 1864 and 1865, on the Rivelin was 20 inches.

4796. Do you mean collected or delivered into the river?—Collected into the reservoir; 39 inches did not fall in those years; in 1864 there only fell 31·880.

4797. Did you secure 20 inches out of that?—Yes; that was in the year 1864.

4798. Have you any other year that you can give us the net result of?—In 1864 and 1865; the evidence given by the engineer as to the amount actually collected, which is undisputed, was 20 inches in the two years for each year, the actual rainfall in 1864 was as I before stated, and in 1865 it was 32·470.

4799. When the rainfall was 39 inches you collected 20 inches, and when it was 32 you collected 20?—When it was 31·880 we collected 20.

4800. How do you account for the difference?—The difference as between 31·880 and 32·470 is not large.

4801. But you gave me 39 inches as the average?—Yes, 20 inches over the 34½ square miles would give, in round numbers, 27,000,000 gallons per day. Out of that they have to supply to the millowners as compensation about 12,000,000 gallons per day, leaving 15,000,000 gallons per day for the supply of the town.

S. F. Holmes, Esq.

6 June 1867.

4802. Is that sufficient for the supply of the town of Sheffield?—The town of Sheffield which is at present supplied has about 210,000 inhabitants, and the 15,000,000 gallons a day would give 25 gallons per head for a population of 600,000.

4803. What is the consumption of water now?—During the year when the average rainfall is anything like 39 inches they can give 12 hours' supply; but during 1864 and 1865 they were only able to give in the autumn of the year for some weeks three days per week, and that only for six or eight hours per day.

4804. When you say 12 hours, do you mean that the pressure is on for 12 hours?—Yes, the pressure is on for 12 hours.

4805. When you had a sufficiency of water was that 12 hours in the middle of the day, or when?—In some districts it varied from six in the morning to six at night, and from seven in the morning to seven at night in the other districts.

4806. That would give to each inhabitant how much?—About 11 gallons per head.

4807. Does that 11 gallons cover the water used for manufacturing purposes?—It does.

4808. Have you found that ample?—No; it is very deficient indeed.

4809. Do you mean for manufacturing purposes or for domestic use?—For both purposes.

4810. What, in your judgment, would be a sufficient supply, having regard to the town of Sheffield as a manufacturing town?—Having regard to the town of Sheffield consuming more water than most towns do for manufacturing purposes, I think we ought not to have less than 30 gallons per head for the population.

4811. There is a large consumption in the grinding trade, is there not?—There is a large consumption for engine power. In all branches of the Sheffield trade there is a great deal of engine power, and of course that consumes a considerable quantity of water.

4812. What is the quality of the water that you are now supplied with?—It is an excellent quality of water.

4813. Is it soft?—Yes, it is from the grit with overlying peat a portion of it, and from the black shale.

4814. Is it at all coloured with peaty matter?—It is until it has been stored in the reservoirs. We have large storage reservoirs, and from thence the water runs down a conduit for some miles to the services, and it remains in some of them for three days before it is used, and the colouring matter to a great extent is taken out.

4815. How long does it take to precipitate the colouring matter?—I should think two or three days would do it, but it is not often you can observe it in the town.

4816. I suppose in floods you get a larger portion?—It is in flood when you do observe it, you do not observe it in the winter season of the year.

4817. Have you any means of turning off the flood and storing the ordinary flow of the river?—In some of the reservoirs we have; in Dale Dyke reservoir unfortunately they had not taken the means of keeping the flood water out of the reservoir, it all had to come through the reservoir.

4818. Are you aware of the process they have now of allowing the water to drop and rush over in case of flood?—Yes, not allowing it to fall into the basin of the reservoir.

4819. You have no such means of separation?—No, we have not.

4820. Prior to this water supply how was Sheffield supplied with water?—Sheffield has always been supplied by a company, the present supply reservoirs which are close upon the town of Sheffield, from 150 feet above the lowest part of the town, were formerly the collecting reservoirs, and the moor and uncultivated land was closer to the town then and those reservoirs were made for storage on the hill sides.

4821. The town of Sheffield has for some time been supplied with the same water, although formerly it was taken at a lower point?—Just so.

4822. What is the effect upon the health of the inhabitants of using this soft water?—We consider that it has a very beneficial effect, our death rate now is very low, and we believe that to some extent is owing to the water.

4823. What do you call low?—About 21 per 1,000, that has been the average for some time.

4824. It has been over 30 has it not?—It has, we have very much improved in our death rate within the last few years.

4825. Do you attribute that to the supply of pure water, or to improved drainage or both?—I think to a great extent to improved drainage. I do not think so much is to be attributed to the water as to the drainage.

4826. How do you get rid of your drainage?—We have constructed a drainage system to carry it below the town, but unfortunately we are throwing it into the river. We introduced a plan two years ago to take it down below. Thorn, which would be some 30 miles below Sheffield, and we tried to induce the towns below in the basin of the Don, Doncaster, Barnsley, and other places in the same watershed to join us in applying for an Act of Parliament in order to take it to Thorn waste and utilize it, but we failed in getting any support. Consequently we have postponed that for the present or else we had a scheme for draining the whole watershed area of the Don into one large conduit, and then conveying the sewage to Thorne waste and there utilizing it.

4827. As to the gathering area have you realized your anticipations of the quantity of water that you would obtain from that 34½ square miles?—The amount actually collected in those two dry years which I think you will find throughout the country, were the driest years that have been known in this country for a great number of years, almost within the memory of man, was 20 inches on upwards of 5,000 acres of gathering ground bearing about the same elevation above the level of the sea as the whole of our gathering area does.

4828. How does the deficiency in quantity arise, is it because your storing power is not sufficient on the capacity of your conduit or what?—We had not sufficient gathering area previous to that. On the Rivelin watershed which I am particularly alluding to that 20 inches of rainfall being collected there we had actually more storage than in most years we could fill. We had more storage competent to the drainage area than is usual.

4829. I understand that you will have storage equal to the water due from 34½ square miles?—Yes, that is so, but that embraces not only the watershed of the Rivelin but the watershed of the Loxley and the Ewden.

4830. You stated, did you not, that you have a great defficiency of supply, therefore, that 34½ square miles is not sufficient for your purpose?—The new reservoirs are not yet constructed. We are actually only taking water now from about 5,000 acres.

4831. The 20 inches which you say has been stored applies to a limited area?—Yes, the area that we are now gathering from.

4832. But you are extending your area, how many square miles?—We are extending our area to 34½ square miles, from about 20 square miles.

4833. That is to say, you are now increasing it to 34½?—Yes.

4834. But how long will it be before your reservoirs are completed?—The latest period for completing the last of the reservoirs is fixed for 1877.

4835. Is that the time necessary for the structural works?—No, they are bound to give us a constant supply under the Act of 1864, that is to say, in 1853 the company bound themselves to give us a constant supply 10 years afterwards, that would have been in 1863. They completed their Dale Dike reservoir in the autumn of 1863, and proposed giving us a constant supply in 1864. Then the disaster happening they came to Parliament to ask for an extension of time for giving us a constant supply, and got their time increased to 1869. They are bound now under

their present Act to give us a constant supply in 1869, and are now constructing two reservoirs, the Strines Dike reservoir and the Agden reservoir; the latter reservoir will be completed in 1869.

4836. Then in 1869 the company will be in a position to give a constant supply?—Yes, if required by the town council.

4837. I suppose they then will be in a position to supply all the water that you require for both trade and domestic purposes?—Yes, they will.

4838. Up to that time, 1869, you will labour under your present difficulties of an insufficient supply?—Yes, if it were to be a dry year like 1864 or 1865 the consequences might be fearful to the town.

4839. The water from those 34½ miles will be more than sufficient, will it not, to supply all the town?—Yes, as I mentioned before it would supply 25 gallons per head to a population of 600,000.

4840. Is there any other town near Sheffield that could be supplied from the same source?—Yes, Rotherham could be supplied from the same source.

4841. Have the water companies power to supply any other town than Sheffield?—No, they have not.

4842. There would be no difficulty from the same gathering ground in supplying Rotherham also?—Not the least.

4843. What steps, if any, do you propose to take to supply the town with water until 1869. The water companies as I understand are relieved from their obligation under the Act of 1853?—Yes, the water companies are relieved from their obligation under the Act of 1853, but they are bound by a clause to give a constant supply in 1869 at the request of the town council.

4844. Is there any part of the town now under a constant supply?—No part of the town.

4845. As an engineer, do you see any difficulties in the application of the system of constant supply?—Not the slightest; it is all natural gravitation. We have got plenty of head for supplying the highest parts of the town.

4846. Do you see any advantage in substituting the constant supply for the intermittent system?—No, except in case of fire. There must be a great waste going on in the constant supply. There is waste in the day time and it is going on in the night as well.

4847. That would depend, would it not upon supervision?—To some extent it would, but in some parts every cottage house has a pipe and they turn the water on for every purpose.

4848. Has every cottage a pipe now in Sheffield?—A great number have obtained them during the last five or six years; a great number have stands in the yards; but that system is going out, nearly all the new cottages a e being erected with the water over the sink stone.

4849. From what I have observed they appear to flock round some standcock to take their supply?—Yes, they do.

4850. Then the houses are not provided with a tap and a separate service?—Until a few years ago the whole of the blocks of cottage houses were supplied with stands in the yards; but the houses erected since and even many of the older ones have had the water supplied in the houses direct in each case.

4851. Has that been under any order of the Board of Health?—No, it is simply the interest of the landlord.

4852. Have they not power to compel the proprietors of the houses to lay on a supply for the houses?—Yes, they have.

4853. And to charge the owner with the cost of the water?—Yes but the Local Board in this case has not the control of the water.

4854. But the Local Board of Health have power to compel the owners of property to apply to the water companies for laying on a supply to each house?—Yes, they have.

4855. And if necessary to charge the owner with the cost of supplying it?—Yes.

4856. Has that been the rule with your Local Board or have they neglected to put in force this power?—They have never had occasion to exercise this power. We have no cognizance of any cottages that are not supplied with water by stands or within their own residences.

4857. Will you state why it is that you now have houses supplied with a direct service, whereas some short time ago the occupiers were obliged to go to a stand-pipe to take their supply every day?—The land owners found it to their interest to do it; people prefer to take houses so. We have many working men in Sheffield, getting very good wages and they prefer to take houses with water in their own house without having to go to a common stand in the yard.

4858. Their self-interest has been sufficient to induce the landlords to adopt the improved system?—It has been so in many cases.

4859. What class of cistern is used generally?—We have a great many cisterns in the yards that are made of brick and cement, and those have a pump in them; they are made of 9-inch brickwork lined with cement and puddled behind.

4860. Those cisterns I presume are in the ground?—Yes, arched over.

4861. Then they insert a suction pipe into that cistern and give them a pump?—They do.

4862. Is that the rule?—It is adopted in 10*l.* 12*l.* and 15*l.* houses.

4863. For a 10*l.* or 12*l.* house, what size would the cistern be?—Various sizes; but there are many put down within my knowledge 9 feet by 4 feet deep, containing 146 cubic feet, which would be about 876 gallons.

4864. How often is the water turned on?—It is turned on every day except in those dry seasons to which we have been alluding.

4865. As a rule, how many inhabitants would occupy a house of 10*l.* a year?—The average in Sheffield is about the same as in most places, five per house, or rather under that.

4866. Then do you give a capacity of between 800 and 900 gallons to a house occupied by five persons?—No, there would be four or five houses to this pump; in those cases the pumps would be in the yard.

4867. The pump is in the yard, and there is inserted in that cistern a suction pipe or several pumps attached to a suction-pipe?—In many cases it is only one pump and they fetch the water from the pump in the yard to which they all have access, and there are other houses in which rather a better class of people live, but not so many of those houses into which several suction-pipes are placed and they draw it from them into each house; there are not many, but outside the town there are some few instances of that.

4868. You do not call that a separate service to each house do you?—It is taken from one common reservoir; that is supposing you have a yard behind a row of four houses.

4869. I understand that you have a block of houses and you form a reservoir or tank made of brick lined with cement to give between 800 and 900 gallons of water which is renewed every day, and that the occupiers of that block of houses, consisting of 6 or 10 houses, as the case may be, have a right in common to the pump or pumps which may be fixed?—Yes.

4870. That is not what we call a separate service to each house?—No; it is not a separate service to each house.

4871. Are there any houses in Sheffield of that class with a separate receptacle for water under the absolute control of the occupier of that single house?—Those that are supplied separately over the sink stone draw direct from the main; they have a tap over the sink where they would do their washing, and that tap is supplied in some instances direct from the main, so that when the water is not on, of course they cannot draw the water, and they have to store it from one time to the other.

4872. During 12 hours of the day, that is from 6 to 6 or from 7 to 7, they would have a constant supply?—Yes.

S. F. Holmes, Esq.

6 June 1867.

4873. It would be constant pressure?—Yes, a constant pressure.

4874. The pressure is simply taken off during the night?—Yes. There are other houses of a larger class which have a cistern in the roof.

4875. Can you tell us the proportion of houses of that class which are supplied with this tap over the sink?—I cannot. There have been a great many put up during the last four or five years.

4876. Has that privilege been abused by the occupiers of the houses?—Not to any great extent.

4877. There has not been much found to result from it?—There is more waste from the common stands no doubt than from the taps in the private houses.

4878. Then in your judgment the principle of a direct supply at constant pressure would be a principle of economy in the interest of the Water Company?—No, I do not think so. There are a great many leakages in the streets, both in the services and in the pipes themselves, and I do not think it would be a source of economy to the company, I think it would be a loss to the Company.

4879. Have you cast mains?—They are cast mains.

4880. How are they jointed?—They are jointed in the ordinary way with lead.

4881. I suppose you, as an engineer, are prepared to state that pipes can be obtained of sufficient strength and perfection to resist the pressure necessary for the constant supply?—There is no question of that at all.

4882. Then the waste is due to the condition of the pipes in Sheffield now?—No doubt it is so.

4883. And if those pipes were put into a proper condition, you think that there would be no waste?—Quite so, from that cause.

4884. If put into a proper condition is it your opinion that the principle of a constant supply would be better, all other things being equal?—I do think so.

4885. In 1869 the company will be obliged to give a constant supply, will they not?—They will.

4886. Will that constant supply be limited to 12 hours a day as now, or will it be 24 hours?—It will be day and night.

4887. In your judgment will it be necessary for the company to repair the pipes or to lay down pipes of a sufficient strength to resist the pressure?—I think so.

4888. And also to attend to the joints between this and 1869?—I think that a great many of the pipes in the Sheffield streets will require renewal before that time, at all events to avoid the immense leakage which must occur unless they do.

4889. In the new parts of Sheffield, where pipes have been laid down recently of sufficient strength and properly jointed, have you heard of any complaints of the waste of water?—I have not. Having the control of the public streets of course the immense number of breakages we have in our pipes in the Sheffield streets come under my notice.

4890. What does that breakage arise from?—It arises I think in the first place from the corrosion of the pipes from their having been down such a length of time, and in the next place of course there is a large head of water and a great pressure upon them. This causes a great many breakages in the streets.

4891. Your pipes are in the subsoil of course?—Yes, they are in the subsoil.

4892. You have no subways, I believe, as they have in Nottingham?—We have no subways.

4893. Do you think that the system of subways would be an advantage?—I do think so. I think that the water ought to be got at without picking up the public carriageways so frequently as we have to pick them up in our town.

4894. With the exception of the decay of the pipes and the want of capacity to resist the pressure, you are in favour of a general system of supply with constant pressure?—I am. I think that when towns can be supplied under constant pressure as easily as is the case at Sheffield, they ought to be supplied. From the large gathering ground that we have available, I think it is imperative that the water company should supply us under constant pressure.

4895. What is your head of water?—Our highest service reservoir is about 400 feet above the lowest parts of the town.

4896. How far is it from the town?—About $2\frac{1}{2}$ miles from the lowest part of the town, the storage reservoirs are at least 600 feet or 700 feet above the service reservoirs.

4897. But your head of water would be from the lowest reservoir?—It would; but the town is increasing above the level of the present highest storage reservoir, and they have contemplated that they will be obliged shortly to construct a storage reservoir at a higher level upon the line of the conduit, and they have obtained power to buy land for that purpose.

4898. Would not 400 feet carry it to the top of any house in Sheffield?—No; the town is increasing up the hill to a higher level, above the present service reservoir in fact, but for the great bulk of the population the head will at least be on an average of 200 feet of height.

4899. Has there been any discussion in the board of health or in the council as to the propriety of taking charge of the water?—In 1864 at the time of the disaster, there was a discussion as to the propriety of doing it, but there was no action taken upon it.

4900. Do you know the capital of the company, I mean the increased capital which will be necessary to enable them to complete their works in 1869?—They sought for a further capital last year of 800,000*l.*, but one portion of the scheme, the watershed of the Little Don, was struck out, and I think it would now be some 400,000*l.* additional. They have had a capital of 1,160,000*l.* prior to the present year.

4901. Then that would make 1,560,000?—Yes.

4902. Do you know what dividend they are paying?—Three per cent. was the last dividend, but it was five per cent. before the accident.

4903. Has the reduction from five to three per cent. been in consequence of the accident?—Yes, it has been in consequence of the accident, and in consequence of the additional capital for paying off the costs of the accident.

4904. Do you see any difficulty in preventing the occupiers of small houses wasting the water by instituting some principle of inspection?—I think they have the power of inspection, and penalties are inflicted on detection; there is no difficulty at all in controlling them.

4905. Do you think that the people of Sheffield would not rise in rebellion against any such inspection?—Certainly not.

4906. (*Mr. Harrison.*) You were asked a question which you did not follow up, which was with regard to your corporation having it in contemplation to take the waterworks; will you tell us what was done with regard to that?—An offer was made to the company during the progress through Parliament in 1864 of the bill asking for powers to raise further capital to pay off the costs of the disaster, but the company did not accept that offer. The offer was made after a resolution was passed by the council in the committee room, but no further action has been taken upon that matter.

4907. (*Chairman.*) What is the scale of charge by the company in Sheffield; are they guided by the rent of the house?—It is about five per cent. on the rental, and 25 per cent. upon that for 7*l.* a year house and under; the rate was fixed by the Act of 1864, including the 25 per cent., and they obtained under that Act an addition to their previous rate, making it 8*s.* $11\frac{1}{2}d.$

4908. Have they power to charge 30 per cent. on the rental?—They have power to charge pretty nearly equal to that upon 7*l.* a year; it really would in cottage houses amount to that.

4909. What I understand you to say is this, that their original power was to charge five per cent. upon the rental of any house?—Yes.

4910. And they subsequently obtained powers to charge 25 per cent. more ?—They did.

4911. Is that 25 per cent. of the five per cent., or what ?—25 per cent. upon the rate which would arise, upon the five per cent.

4912. Therefore it would be between six and seven per cent. ?—Yes.

4913. Is that for small houses, or is it a scale operating on all the rentals ?—It is a scale operating on all the rentals. The rate on 7*l.* and under is 8*s.* 11½*d.*; 7*l.* and under 8*l.*, 10*s.*; 8*l.* and under 10*l.*, 12*s.* 6*d.*; 10*l.* and under 12*l.*, 15*s.*; 12*l.* and under 15*l.*, 17*s.* 6*d.*; 15*l.* and under 18*l.*, 20*s.*; 18*l.* and under 20*l.*, 22*s.* 6*d.*

4914. Then the rule is carried out throughout ?—Yes, for houses of 100*l.* and upwards it was 3 per cent. upon the rental under the Act of 1853, and under the Act of 1864 it was 3¾ per cent. upon the rental.

4915. What do they charge for manufacturing purposes, what they call their wholesale customers ?—10*d.* per 1,000 gallons, and 25 per cent. upon that 10*d.*, making 1*s.* 0½*d.*

4916. (*Mr. Harrison.*) Having reference to the special inquiry of this Commission what are the chief points to which you wish to direct our attention at the present moment as regards Sheffield ?—The chief point to which I should like to draw the attention of the Commission is the want of supply for sanitary purposes. They have the power of charging us like other consumers 1*s.* 0½*d.* per 1000 gallons for the water used in watering the streets, or flushing the sewers, or anything of that kind. We should have power under the Local Government Act to take them to a reference upon the question of rate, but still I think it would be very desirable indeed that Parliament should itself have fixed a lower rate for the water used for sanitary purposes.

4917. That is substantially the point to which you wish to direct the attention of this Commission ?—Yes, it is.

4918. Bearing on that point you are aware, I presume, that in several towns such as Glasgow, Manchester, and Liverpool, the corporation have taken the waterworks into their own hands ?—I am aware of that.

4919. And with beneficial results in all those cases ?—Yes, I believe that to be so.

4920. At present it is quite an open question, is it not, in the case of your corporation ?—I am afraid it is a question of such magnitude that it will frighten the Sheffield people for a great number of years; you see the immense capital that they have, and the increased capital, owing to the disaster, of something like 400,000*l.*, that is dead capital, and it would require an immense sum to purchase their waterworks.

4921. Looking at the position of Sheffield there is hardly any town in the kingdom, is there, that is better situated for getting a supply of water ?—There is no town in the kingdom better situated for getting it by natural gravitation. We have very valuable works on the streams, and it enhances the cost of the water to the inhabitants to compensate the owners of those works by compensation reservoirs. I believe that the cost of those compensating reservoirs increases the cost of the water to the inhabitants more largely than in most places.

4922. Are not all of those valleys open to you going up towards Chesterfield ?—Yes, those valleys going up towards Chesterfield direct are open to us, but the water is not so pure. There are some beds of coal and it is being got in several places, and there is a great deal of ochre water thrown into the streams which renders the water unfit for domestic purposes.

4923. If it had not been for the failure of the Dale dyke reservoir you would before this have had an abundant supply ?—We should have had an abundant supply of water of first-class quality. There can be no dispute as to the quality.

4924. Then the point upon which you really feel aggrieved is the price which the company under their Acts of Parliaments have the power of charging for sanitary purposes ?—That is so

4925. I suppose that is a point which you have contested before the committees of the Houses of Parliament this session ?—No, not this session. We contested the 25 per cent. most strongly in 1864, but it was given for 25 years in spite of our opposition. I will read to the Commission the resolution passed by the Council in 1864. "Resolved that in the opinion of "the Council it is desirable that they should purchase "on behalf of the inhabitants of Sheffield, the works "of the Sheffield Waterworks Company upon sums "hereafter to be agreed upon rather than an advance "of 25 per cent. should be sanctioned upon the "present water rate."

4926. (*Chairman.*) Were not the water company before Parliament when that resolution was passed? Yes, "Resolved further that it be an instruction to "the committee appointed to oppose the Sheffield "Water Company's Bill, and they are hereby requested "to communicate the above resolution to the Sheffield "Waterworks Company for the purpose of ascertaining their views thereon, and at the same time offer "to purchase the waterworks on the following terms, "namely. Upon terms that shall secure to the company as a consideration for such purchase either "perpetual annuities equal in the aggregate to 2*l.* per "centum per annum upon the present share capital "of the company and an indemnity from their mortgage debts and from their liabilities incurred by the "bursting of the Dale Dyke reservoir, or such a sum "equal to the value of the undertaking immediately "before the inundation, after deducting therefrom the "sum of 40,000*l.* being the estimated cost of reconstructing the said reservoir, and also deducting the "amount which shall be paid by the company for "damage or compensation in consequence of the said "inundation, on which shall be assessed for damage "or compensation consequent on the said inundation, "and also providing for the transfer to the council "the mortgage debts of the company, the amount of "such mortgage debts not to exceed the aggregate "amount of the principal monies due by the company "on mortgage or bond, or to take to the works on "terms to be settled by arbitration if Parliament "will so permit, and if the company will not accede "to any of the above terms whether they would be "disposed to transfer such works to the corporation "on any other terms."

4927. (*Mr. Harrison.*) Not having been successful in accomplishing that object, what can you suggest that this Commission would be able to do to relieve you in any way ?—I am afraid that after Parliament has given them the 25 per cent. and they upon that clause having borrowed a large amount of capital to pay the compensation due to the sufferers from the disaster, it is a matter which it would be difficult to manage.

4928. Taking the towns that lie on the river below you, for instance Rotherham or Doncaster, or going further on, Thorne, and then going to the east of all Goole, would not this water company when they have completed the whole of the works which are now authorized have an abundaut means of supplying the whole of those towns with water ?—They would, I believe, on the present population, and if they had not sufficient, there is still further available gathering ground for increasing those works.

4929. Has it ever occurred to you that in the case of a number of towns so situated as those I have just mentioned, and, of course, all the intermediate villages the grouping together of a large district might be a desirable thing ?—If the district were sufficiently closely populated to warrant the expenditure in pipes running from one district to another it would no doubt be a great advantage. I believe, that ultimately the whole of the valley of the Don from Sheffield to Goole will be so thickly populated, in fact, within a very moderate number of years as to warrant such an expenditure as that, and it would pay well to take the water from our hills down there.

4930. In the consideration of the question of purchase by your corporation did you ever take into

S. F. Holmes, Esq.

6 June 1867.

account the possibility of such an extension?—We have not done so.

4931. The Agden reservoir was about half completed at the time of the fall of the Dale Dike, was it not?—Yes, it was.

4932. Is it now nearly completed?—It is getting very rapidly on. They are proceeding very rapidly with that reservoir in order to give us a supply in 1869.

4933. They have altered their mode of induction pipe, have they not?—Yes, they have, and they have strengthened the embankment also, and widened it out.

4934. Then the whole of that water which you now get from your Rivilin reservoir there is as pure as anything can be?—It is.

4935. And even when you go up to Dale Dyke you can get almost into the immediate neighbourhood of the millstone grit?—Close to it, it crops out close to it.

4936. As far as your prospects go you have water of quantity and quality infinitely more than you can possibly use?—Yes, and we have new Parliamentary powers also for all we can possibly want.

4937. The only complaint you have is that for sanitary purposes you to have pay too high?—Yes, and also as regards the rates, there is a very strong feeling in the town that we pay too much by 50 per cent. for our water.

4938. The only remedy for this appears to have been that the town should have purchased them?—Yes.

4939. Is Mr. Hawkesley acting now as engineer to the Sheffield Waterworks?—Yes, and I must admit that the work now at Agden looks to be of a very different character from the manner in which the Dale Dyke reservoir was constructed. They are certainly doing it now on excellent principles, and they are proceeding very carefully with the work and rapidly also.

3940. (*Chairman.*) Are they using other materials than those used in the Dyke Dale which gave way, or are they simply increasing its base?—They are increasing its bulk, and they are managing it so as to put next to the puddle a comparatively impervious material to support the puddle before it was thrown in indiscriminately, but now they are putting it in layers upon the bank, and raising it gradually.

4941. What is the measurement of the top square of the bank for the incline?—At the top it would be something like 30 feet when it is finished.

4942. How much at the bottom?—At least 500 feet or 600 feet; it is one of the strongest embankments I have ever seen.

4943. (*Col. Harness.*) What is the greatest height?—90 odd feet.

4944. (*Chairman.*) Are there any other points that you are authorized to lay before this Commission besides the question of the 25 per cent?—There has been a strong feeling in the town against it, but I do not think it is much use now exhibiting it.

4945. If Parliament have sanctioned it, and the company have borrowed money on the strength of that Parliamentary right, it would be scarcely possible for this Commission or any other body to interfere with it?—No; but there is another question which has lately arisen.

4946. Has the town of Sheffield any idea of going to Parliament for compulsory powers to purchase the water company?—Not the slightest idea at present, it has never been mooted.

4947. What is the rateable nature of the property in Sheffield?—It was 544,000*l.* in the year 1866.

4948. What rate of increase is going on in Sheffield?—In 1848 the rateable value was 272,161*l.*; in 1857 371,679*l.*, and at the end of 1866, 544,000*l.*

4949. I think you were about to state some other point to which you desire to call the attention of the Commissioners on?—The company are now requiring the council to put down at each stand for watering the streets a meter and the meters will cost 20*l.* each.

4950. Have they the authority of Parliament to call upon you to do so?—They have; but the meters will cost 20*l.* each, and they offer either to allow us to put them down at our own cost or to put them down themselves and charge us 10 per cent. upon the amount as rent, It is a very serious matter when you come to have 50 or 60 stands with meters costing 20*l.* each.

4951. When you speak of stands do you mean cab stands, or what?—In fact you may call them sluices in which they insert pipes to take water from the mains for watering the streets and to which they attach stands.

4952. You mean for sanitary purposes?—Yes, we require 50 at the present time; that would be 1,000*l.*, of course 10*l.* per cent. upon that is 100*l.* for rent of meters only, which is a very serious question.

4953. Are you under a contract with the company to pay them so much for all the water that you require for those purposes?—We are negotiating for a contract.

4954. How have you paid the company for the water used for sanitary purposes up to the present time?—It has been more by guess more than by anything else; of course they know what each of the barrels hold and they know the number of times per day that it is filled and that measures the water.

4955. Have you had no agreement between the company and the corporation?—No never.

4956. Has the amount varied from year to year?—Yes very much.

4957. And do they allege that you have been using more than you ought and hence the necessity for those meters to check the increased consumption?—They do not; they simply allege that it is now time that we had some arrangement, and they think that as a trading community they are bound to measure out what we do take.

4958. What do they charge you per 1,000 gallons?—We have no fixed price, we are negotiating that at the present time.

4959. Failing a satisfactory settlement between you and the company have you any right of reference?—We have the right of reference under the Local Government Act, and there is a clause also in their Act of 1864 enabling them to sell water to the town at a less price than to other consumers.

4960. Has the arbitrator power under that general reference to fix the price at which the town should be supplied?—He has. This is the clause in the new Public Health Act, the 11th and 12th of Victoria, chapter 63, section 75, "In case any difference shall "arise as to whether the water which any such com-"pany is able and willing to supply or lay on is "proper and sufficient for the purposes for which it "is required by the said Local Board, or whether the "purposes for which it is required are reasonable, the "same shall be settled by arbitration in the manner "provided by this Act."

4961. Are you quoting from the Board of Health Act, the General Act?—Yes.

4962. Which Act you have adopted?—Yes.

4963. Is there any other point which you wish to bring before the Commission?—Not any that I am aware of.

The witness withdrew.

Mr. JOHN JACKSON examined. *Mr. J. Jackson.* 6 June 1867.

4964. (*Chairman.*) Are you the chief constable of Sheffield?—I am.

4965. Are you desirous of making any statement to the commission?—No, I do not know that I could really add anything to the evidence already given by Mr. Holmes, the borough surveyor. I have with me a report which shows the condition we were in in 1864. I was desired by the town council to obtain information and to make that report. The information I furnished in detail, but that report is a summary of it.

4966. Do you desire to put this in?—Yes, I desire to put it in.

4967. This is a letter signed by "J. Jackson, chief constable," addressed to the town clerk, dated the 10th of October, 1864?—Yes.

4968. And it embodies the substance of your detailed return?—It does.

The witness delivered in the following paper.

John Yeomans, Esq., town clerk.

SIR, Town Hall, Sheffield, October 10th, 1864.

WITH reference to the resolutions of the committee appointed by the Town Council, "To consider the failure "or neglect of the Waterworks Company to supply water "according to the requirements of the law," I directed four officers to call at a number of the principal manufactories in the borough, and they have obtained the information contained in the returns transmitted herewith.

The officers report having visited 192 manufacturers, 81 of whom however are wholly, and 22 partially supplied with water from sources independent of the waterworks company: and of the 89 wholly dependent upon the company, 34 state that their workmen have lost nothing in consequence of the deficient supply, whereas, the remaining 55 say, the 4,399 persons employed by them, and renting power of them, sustain a loss in the aggregate of 1,522*l.* per week. Twelve manufacturers have sunk wells, and eight are leading water in barrels from different places to enable them to keep their engines and machinery working.

In the under-mentioned streets and places, water can only be got from the company's mains for four hours each Monday, Wednesday, and Friday, viz.: the Market Place, West Street, Glossop Road, Brook Hill, St. Philip's Road, Allen Street, Broad Lane, Westbar Green, Westbar, Gibraltar Street, Penistone Road, Langset Road, Walkley, Philadelphia, Green Lane, Allen Street, Corporation Street, Woodside Lane, Pitsmoor, Burngreave Road, Nottingham Street, Brunswick Road, Carlisle Street, Tinsley Road, Wicker, Blonk Street, Broad Street, Park, Cricket Road, Shrewsbury Road, Suffolk Road, Leadmill Road, Pond Street, Brown Street, Eyre Street, Matilda Street, top of Ecclesall Road, Devonshire Street, Eldon Street, Campo Lane, Paradise Square, Bank Street, Snig Hill, and the streets and places adjacent thereto, whilst in other parts of the borough it is only procurable for a like period each Tuesday, Thursday, and Saturday, This limited supply has been continued since 29th August last.

Householders generally complain of the inconvenience to which they are subjected by reason of their being unable to procure water each alternate day. Many have no suitable vessels in which to store it, and others allege that it becomes impure and unfit for domestic use when kept in their houses from Friday till Monday. Nearly all agree in saying that it would suit them much better if they could get it for an hour every day, instead of four hours on alternate days. Publicans especially complain of its impurity after being kept, and such as have country horses put up at their houses are unable to procure it in sufficient quantities.

Mr. Hicks' property at the top of Woodside Lane has been entirely without water for six or seven weeks, and the occupiers have been obliged to fetch it from Harvest Lane and other places.

I have the honor to be, &c.,
J. JACKSON, Chief Constable.

4969. (*Mr. Harrison.*) Is it your opinion that if the corporation had the entire control of those works in their own hands you would be able to apply the water for sanitary purposes more beneficially than you do now, do you feel hampered by the amount which you are obliged to pay for it?—Partially we do. Of late years we have not been able to get it in sufficient quantities.

4970. (*Chairman.*) In the year 1869, when you will have an abundant supply, would you have far more freedom in the discharge of your duty if the water were under the control of the municipality instead of a joint stock company?—No, I do not know that I should. It would be a mere question of price between the corporation and the company. If they had a sufficient supply of water and would allow me a sufficient quantity for sanitary purposes I should not feel in any way hampered.

4971. I find by the letter addressed to the secretary of the Commission by the town clerk that the resolution of the Improvement Committee is to this effect. "That the borough surveyor and chief constable be "requested to proceed to London to give evidence "on the present state of the water supply of Sheffield, "and that they be accompanied by Mr. Councillor "Ironside and the town clerk." The town clerk is here, and I merely ask whether he desires to make any statement to the Commission?

(*Mr. Town Clerk.*) I am obliged to the Commission for the offer, but I have no authority to make any statement.

The witness withdrew.

ROBERT WILLIAM MYLNE, Esq., examined. *R. W. Mylne, Esq.*

4972. (*Chairman.*) You are a civil engineer and architect?—I am.

4973. And also a Fellow of the Royal Society and Member of Council of the Geological Society?—Yes.

4974. Have you published some contour maps of the metropolis?—Yes; I published them 10 years since.

4975. Are you connected with any Water Company?—I am engineer to one at the present time. The Limerick Waterworks is under my charge.

4976. (*Mr. Harrison.*) The New River was under your father's charge for a good many years, was it not?—My father was engineer to the New River Company for upwards of 50 years, and my grandfather 42 years before him.

4977. (*Chairman.*) During your father's term of office did you take any part in the engineering works connected with the New river?—I at no time held any office under the New River Company, but for 20 years I had been associated with my father in all the works connected with the New River. Since his retirement in 1861 I have had no connexion with the New River Company's works.

4978. Can you state the power of supply from that source prior to 1861 when you were connected with it?—I do not think I can state the exact quantity supplied in 1861 but I know that at certain periods the quantities were made out for Parliamentary purposes, and they are in print. I assisted my father in 1854 in making out a return for the previous year.

4979. What quantity were they able to supply at that date?—Their supply amounted to an average daily quantity of 17,537,396 gallons.

4980. Have they taken any steps for the purpose of increasing the supply of the New River from the river Lea since the year 1853?—Yes; the New River has been considerably enlarged, and its length shortened from 35 to 22 miles. I may mention, that when the Parliamentary Inquiry as to the condition of the supplies of the several companies took place in 1851 and 1852, works were proposed and powers were obtained for carrying out extensive works which the New River Company executed at great cost between the years 1854 and 1857. At that time I entered into the question with my father of reorganising the entire works of the New River Company, in which Mr.

R.W. Mylne, Esq.

6 June 1867.

Lindley of Hamburgh also assisted professionally. Previously the New River Company supplied by gravitation from the level of the New River Head a very large portion of the city and all the low parts of their district. But the new works were designed by dividing the district into three distinct steps or levels of from 70 feet to 100 feet in height, each level having a service reservoir at its head containing a quantity based upon about 24 hours' consumption, the object of those reservoirs being to give a uniform pressure over the district, and to meet the increased draught during the earlier part of the day. Those reservoirs were carried out in three distinct terraces, and were supplied by steam power, raising the water from a series of newly constructed filter beds. I have a map here on which I can show to the Commission the district of the New River Company and the general features and situation of the reservoirs (*producing a map and explaining the same.*) This map is a contour map of 10-feet levels of the metropolis extending from Kew to Woolwich.

4981. Is the area coloured red, that which the New River Company supplies?—The areas coloured on this map do not represent the seven companies separately. they represent the New River in red and the East London in purple. The West Middlesex, the Grand Junction, and the Chelsea are united in one colour, green. On the south side of the river the Southwark and Vauxhall and the Lambeth Company are also united and are coloured orange. The map which I published in 1856 represents the seven companies in separate colours (*producing another map*). On this published map the New River district is coloured red and as I said before from the level of the New River running as a contour line along to the New River Head they supplied by gravitation all the lower portions of the city, Hoxton, Kingsland, and along the Strand. In a few instances where the houses were very high they used to receive extra pressure. The reservoir which is called the High Pond, at Claremont Square supplied a certain portion near and around the New River Head and away towards the west. There was one other small reservoir at Camden Hill and another at Tottenham Court Road, but independently of those there were no other service reservoirs. At Stoke Newington there were two subsiding reservoirs 43 acres in extent, which received the New River water, and passing through them flowed on to the New River Head. In 1852 the new works were designed, the gravitation from the New River Head was abandoned, and the Claremont Square reservoir was heightened 10 feet and enlarged and covered and served by engines at the New River Head as before. That is the lowest reservoir now actually supplying, as far as I am aware, any portion of the New River district. Its level is 126 feet above Trinity high-water mark, the highest services reservoirs are 414 and 433 feet.

4982. I presume the object of distributing those reservoirs over the district was to equalize the supply?—The object was to obtain an average pressure of from 60 to 70 feet in the several parts of the districts, and the design anticipated the adoption of a supply under the constant system.

4983. Can you state whether any reservoirs have been formed in the upper part of the Lea for the purpose of storing the storm waters so as to increase their volume?—I desire presently to speak specially upon that point. My answer to that, so far as the New River is concerned, is that no large reservoirs have been formed for storing the flood waters of the Lea. The East London Company have made reservoirs in the valley of the Lea, low down, for storing to a small extent the freshes.

4984. Do you see any difficulty in forming reservoirs so as to increase the volume of the New River?—Upon that subject, after describing any points with regard to the metropolitan district, I should propose to read some notes in explanation of a proposed scheme for storage.

4985. Will you explain to us first the quantity that you are at present able to supply; secondly, how you propose to increase that supply; and thirdly, what is the character of the water which you are supplying?—In the first place, not being officially connected with the New River Company, I can only state what their present quantity is from the evidence which has lately been given before the Pollution of Rivers Commission, and also returns given into the committee which is now sitting at the House of Commons. In 1853 the quantity supplied by the New River and East London Companies was a daily average of 29,528,385 gallons.

4986. As an engineer, do you see any difficulty in forming reservoirs in the upper part of the River Lea to store the storm water so as to utilize it and increase general volume?—Upon that point I had perhaps better read a statement which will briefly explain my views.

4987. Can you shortly state whether as an engineer you see any difficulty of forming reservoirs at a given point or points, and storing a sufficient quantity of water to increase considerably your capacity of supply?—In reference to the upper tributaries of the Lea, on the Lea proper above Hertford, there are difficulties in obtaining sites for making reservoirs that would be likely to be sound and efficient. I have here a map showing a scheme which I should propose to carry out, which will bring 70,000,000 gallons into London (*producing another map*). I do not mean 70,000,000 gallons additional to the present supply, but by doing away with the present New River intake and the East London intake and consolidating the two companies, so far as sources go, there can be brought into London from storage reservoirs made on the London clay, the detail of which I can explain if necessary. The scheme would give for the East London districts 30,000,000 gallons per day by gravitation from high-level reservoirs delivered on Stamford Hill at the level of 112 feet above Trinity high water mark.

4988. Will you first describe your area, and then the rainfall due to that area?—I have not prepared any calculations based on the data of rainfall, but upon gaugings and observations on the actual volume flowing down the Lea. I would first say that it is to be gathered from various official documents that the New River Company during the past year abstracted from the river Lea an average daily quantity of about 18,000,000 gallons of water at their point of intake, one mile and a half below the commencement of the navigation of the river Lea at Hertford, and the East London Waterworks Company from the same river abstracted at a point near Tottenham, 20 miles below Hertford, an average daily quantity of nearly 19,500,000 gallons of water, making in all 37,500,000 gallons taken during the year 1866 from the river Lea for metropolis supply. The first-named quantity is conveyed by gravitation along the New River open aqueduct, 22 miles in length (and in part by pipes), into reservoirs at Hornsey and Stoke Newington, at the level of about 87½ feet above Trinity high-water mark; and the East London quantity is conveyed along an open conduit, 1¼ mile in length, to reservoirs at Lea Bridge, at the level of 7½ feet above high water, making a difference of level between the two companies stations of 80 feet. Besides the quantity derived by the New River Company from the river Lea, there was obtained from the Chadwell spring and other sources about 5,000,000 gallons, making altogether a total daily supply to the metropolis during the past year by the two companies of 42,500,000 gallons, and this quantity was distributed amongst a population of 1,500,000 inhabitants, representing a moiety of the entire population of the metropolis. As respects the watershed area and population comprised within the Lea basin, above the respective points from which the two companies draw their supplies, it has been ascertained from recent examination that above the New River intake the area is 264 square miles, with a present population of about 73,500 persons, or 278 per square mile; and the East London Company an *additional* drainage area of 219 square miles,

including 79,500 inhabitants, or 363 per square mile; the total being 483 square miles, with a population of 153,000 persons down to Ponder's End, below which point the East London Company have diverted all further drainage from entering that part of the Lea, from which their supply is derived. The principal streams forming the tributaries of the Lea consist, in the upper division of the Lea proper, the Mimram, the Beane, and the Rib, all of which unite and flow down to the point of the New River intake; and the Lea is further augmented in the lower division by the Ash and the Stort, at the junction of which latter river the entire volume passes through Feilde's weir, situated two miles above Broxbourne. I would wish to mention that the quantity which I propose to take from the gathering ground, which I have marked green on the map, is based not upon rainfall but upon measurements taken at Feilde's weir.

4989. Then that is the net result of what finds its way into the river?—Yes. I do not in any way touch upon the question of rainfall; I take the quantity as ascertained at Feilde's weir.

4990. How often have those gaugings been made? In the years 1851 and 1852 some careful gaugings of the daily discharge at Feilde's weir were carried out by Mr. James Simpson, as umpire between Messrs. Beardmore and Smith, the arbitrators appointed to determine the millowners interest arising from a scheme, under the advice of the late Mr. Rendel, of disposing of the surplus water of the river Lea. Although there was no further necessity for continuing the gaugings, they have been regularly kept and recorded, under the superintendence of Mr. Beardmore, the engineer to the river Lea Trust, who it is to be hoped will shortly collate the details and publish them, as a valuable addition to his already extensive information on the flow of rivers. I am informed that Mr. Beardmore has already given in evidence to this Commission the yearly returns of those gaugings, but he has permitted me to look carefully into the monthly and daily returns, by which means I have had the opportunity of ascertaining the surplus and deficiencies on every day over each year. From an examination of these returns it appears that in the Lea valley two periods of great drought during the past 17 years have occurred, viz., in the years 1858–59, and 1863–64–65. The discharge at Feilde's weir due to the watershed area of 416 square miles, [exclusive of Chadwell spring,] was on the average during the respective periods very nearly alike. That is to say, 1858–59, and 1863–64–65, were nearly the same, and although it was so extremely dry in 1865, the average of the three years exceeded that of 1863 and 1864.

4991. That was accounted for by the fact of the springs not being exhausted?—Yes, it was chiefly accounted for by the fact that there were several more months of continuous drought in 1863 and 1864, than in 1864 and 1865. The average discharge for the two periods of great drought was 7,860 and 8,040 cubic feet per minute respectively, but the average of the two years 1863 and 1864 was below that point, and did not exceed 7,355 cubic feet, a quantity equal to 66,000,000 gallons per diem. The yield, however, of the three consecutive driest months in 1864, viz., August, September, and October fell to as low an average as 3,980 cubic feet per minute, and if from this be deducted the amount to which the Trustees of the river Lea have a prior right for the maintenance of the upper division of the navigation, viz., 400 cubic feet per minute, it would leave an available quantity during those three months for valley uses, and water supply of only 32,000,000 gallons per diem, a quantity less than the average daily abstraction during the past year from the river Lea by the New River and East London Water Companies. Below Feilde's weir down to Ponder's End there is an additional area of 67 square miles of drainage into the Lea, but it is chiefly of a low-lying clay country considerably populated, which would yield but a small additional quantity in very dry seasons. There are, however, some copious springs which rise between Feilde's weir and Broxbourn which augment the river to the extent in dry weather seasons of about 6,000,000 gallons per diem. It has been stated that the mean discharge due to Feilde's weir of the two successive driest years over a series of years, amounts to 66,000,000 gallons per day. This quantity may be divided under the following heads, 1st, the upper division above the New River intake, 45,000,000; 2ndly, the Lea below Ware together with the Ash and the Stort, 13,000,000; and thirdly, from springs rising between Amwell and Rye House, 8,000,000, making together 66,000,000. I may observe that these quantities are based upon various experiments and observations which have been made at different times, and also upon evidence which has been given upon the subject. The tributaries yielding the volume due from the upper division (264 square miles in extent), give a much more uniform and regular flow throughout the year than those below, and heavy floods seldom occur, arising chiefly from numerous springs issuing from an extensive chalk district, the greater part of which is covered with large tracts of sand and gravel which act as a permeating medium of storage, equalizing the flow and giving their maximum discharge in the summer season. In the second division (152 square miles) the river Ash runs through a chalk and clay district, and the floods are moderate, but the Stort drains an area consisting almost entirely of tertiary and drift clays, and is subject to great freshes in wet seasons, and is practically dry at times of extreme drought. As respects the springs between Amwell and Rye House, they vary in volume and are affected in colour in wet weather, but their discharge is highest in summer, and those between Hoddesdon and Broxbourn below Feilde's weir are of a much more permanent character, probably arising from a considerable extent of drift area to the westward. The origin of the whole of them, however, it is not improbable may be attributed to a local change in the dip of the chalk, consisting of a gradual depression along the escarpment of the tertiaries extending over 10 miles or more, from Hatfield eastward by Bayford and Rush Green to Rye House and Hoddesdon, at an inclination of about 20 feet per mile, the line of which is nearly at right angles to the general dip of the chalk basin. There is, however, another feature lying beyond the watershed drainage area of the Lea which there can be little doubt has an important bearing on the source of these springs, viz., the existence of an isolated clay catchment basin of 23 square miles, which has no direct surface outfall, the central and lowest part of which is between North and South Mims where the surface is chalk, and several swallow-holes exist in the locality which receive and absorb the drainage water of the district. The natural tendency in this case would be for the waters to flow in the direction of the general dip of the chalk basin, but from the inclination of the strata towards the east, there can be no doubt a considerable portion of the water is carried off in that direction. There is a small ridge at North Mims separating this catchment basin from the Colne valley (*pointing to the map*), the entire volume of the drainage shoots down from off the clay lands on to the chalk, and pours into numerous swallow-holes and entirely disappears; within the last fortnight floods came down here (*pointing to the map*) with greater force than has perhaps been known for several years, it attained a depth of 10 feet over a small area of ground, and rose to within a few inches of the top of the ridge, but it all passed away into the swallow-holes, and does so continually.

4992. (*Mr. Prestwich.*) Your impression is that the water which disappears at the Mims issues again in the form of springs in the neighbourhood of Hertford?—Largely between Hertford and Hoddesdon, but a considerable portion of it also finds its way towards the south-east in the direction of the dip of the basin.

4993. Would it not be more likely to flow towards London, that being the point at which the chalk is at

R. W. Mylne, Esq.

6 June 1867.

its lowest level?—I think not, for the chalk is very flat for some miles before reaching London.

4994. (*Mr. Harrison.*) Is the dip of the chalk a regular one, or is there any fault in it?—I think there is no fault but a disturbance to the eastward.

4995. (*Mr. Prestwich.*) Would not a great deal of this water which disappears in the neighbourhood of the Mims go to supply the wells in London?—A portion of it no doubt. At the wells at Cheshunt the chalk is reached, but the supply is not large. At a well at North Mims only a few yards within the Colne watershed, the water stands at 60 feet from the surface, although to the east of the ridge 10 feet of water accumulates at times above the surface, sweeping away into the swallow-holes. How far that is a ground for supposing that this area supplies the springs I do not know, but I advance that as a probable origin. The source of the Chadwell spring, though deep seated, may possibly be influenced from the same circumstances, and its volume, though variable, may be taken at about 4,500,000 gallons per diem. It flows, together with the water abstracted from the Lea, along the channel of the New River, which has bays or stop-gates on its course to restrict and regulate the flow, giving a velocity to the stream of from three quarters to one mile per hour throughout. As regards the fall of the river, the difference of the level of its bed between Ware and Enfield, 13 miles in length, gives an average of about 4½ inches per mile, and from thence to the Hornsey reservoirs, a distance of 6½ miles, a fall of 11 inches per mile. That difference in the fall has a bearing upon the scheme, because I adopt the lower length of the channel of the New River to carry a greater volume of water than at present. The inclination of the surface of the valley of the Lea from Hertford to Hoddesdon falls at the rate of four feet per mile. The width of the valley in the upper portion is on an average about half a mile, and its subsoil consists of from 12 to 15 feet of coarse calcareous gravel overlying chalk, with a superstratum of loamy clays. These gravels contain a large mass of water, which boils up on being disturbed, evidently deriving its source from subterranean springs, which, issuing from the eroded sides of the chalk and flowing down the valley in the gravel, give rise to a few surface springs, but the greater part of the water never appears above but is absorbed and soaks away in the outcrop of the sands underlying the London clay, which commences southward in the valley between Hoddesdon and Broxbourn. This volume, it is suggested, might with advantage be collected for water supply, as it is now lost under the London clay, and trends away to a great depth in a south-easterly direction towards the mouth of the Thames. The question of storing the freshes of the upper tributaries of the Lea by the construction of impounding reservoirs has been frequently discussed, but only on one occasion has the matter been put forward in a definite and comprehensive shape. In the year 1852 the late Mr. Rendel in association with Mr. Beardmore designed two large reservoirs on the Lea above Hertford, also one on the river Rib, and a third on the Ash, the object being to obtain an average daily supply of 90,000,000 gallons. Parliamentary notices were given and a bill deposited for this scheme, but it dropped from the want of combination of various contending interests. Since that period no suggestions have been made to store in the upper tributaries of the Lea, and it has become a generally accepted opinion that there would be some difficulty in finding sufficiently extensive sites on impermeable soils for the requisite reservoir areas and this has led to the statement that if the freshes are to be stored it must be done at a point in the valley below Broxbourn, where the London clay commences. Mr. Beardmore has given some evidence upon that point, and it is stated in the Report of the Pollution of Rivers Commission that if the waters are to be stored and impounded they think from the evidence given that it can only be done by making a large reservoir at that locality. The whole of the water in the Lea except such quantity requisite for the maintenance of the navigation became under an Act in 1855 the property in equal moieties of the New River and East London Companies, and all the watermills on the course of the river below Ware have been purchased and now belong to them and the Lea Trustees, excepting the Government Ordnance factory and two other proprietors; the consequence, therefore, from the companies being masters of the water rights of the valley impounding reservoirs could now be carried out with more unity of purpose and less interference of vested rights than formerly. It being proved that in very dry seasons some difficulty is experienced in obtaining out of the river the full draught at present required by the two companies in the summer months, and seeing that the East London Company have sought powers this year to increase their supply from the River Thames above Kingston to the extent of 10,000,000 gallons per day, and that the present consumption of the New River Company amounts to the full extent of their powers and produce of the Lea in its minimum condition at Ware, and are thereby chiefly dependent for future increase on springs and chalk wells situated *within* the basin itself, and further from the recent Inquiry on the condition of the Lea by the Commissioners for preventing the pollution of rivers, it is not unlikely that extensive drainage works will be required; whether taking all these circumstances into account the time has not now arrived when the subject of impounding reservoirs should not be seriously entertained, and thus obtain an increased and improved quantity from the Lea valley for the supply of the present and future wants of the northern and eastern portons of the metropolis. To store the freshes below Broxbourn at the level of about 60 or 70 feet above Trinity high-water mark would only embrace a means of gravitation to the present works of the East London Company and would involve a lift of from 30 to 40 feet into the level of the New River, and would also necessarily involve expensive works for the removal of the drainage of the upper towns both on the Lea and the Stort. In contradistinction to the view recently put forward, that no means of storage could profitably be carried out without descending as low in the valley as Broxbourn or Waltham it is herein suggested that a considerable quantity from the upper tributaries mostly of pure spring water might be diverted and transferred by gravitation from a point above Hertford direct to convenient sites for reservoirs at Enfield Chase on the London clay beyond and altogether outside of the watershed of the upper portion of the Lea basin, and a further quantity might be impounded within the basin in the valley of the Rib. It is proposed to make diversion cuts on the before-named four tributaries, viz., the Lea proper, the Mimram, the Beane, and the Rib, and convey the collected quantities along an artificial channel to a point in the valley 2½ miles above Hertford; the total contributing area would be 246 square miles, giving an average daily yield of 43,000,000 gallons, but it is only proposed to take 40,000,000 gallons, and to convey that volume in a direct line to London through a tunnel and covered channel 5½ miles in length into reservoirs proposed to be made on Enfield Chase. The two proposed reservoirs to be made, into which the waters would gravitate, will cover an area of 270 acres, and will contain, including the tunnel, 1,391,000,000 gallons, with a top-water level of 130 feet above Trinity high-water mark and a maximum depth of 37 feet of water. I have brought with me a plan showing the reservoirs mapped in detail on the large scale Ordnance Sheets (*producing a plan and explaining the same to the Commissioners*). To command such level from the four tributaries it would be necessary to form diversion cuts, first at the level, on the Lea a few yards below Woolmers Park; secondly, on the Mimram, from the lower part of Panshanger Park above Hertingfordbury; thirdly, on the Beane, from a point some distance below Watton Woodhall Park; and fourthly on the Rib above Wades Mill. In order to increase the extent of reservoirs on Enfield Chase, and

to bring a higher water level into use for distribution it is proposed to construct four further reservoirs at the additional height of 36 feet and to lift into them by steam power a considerable portion of the collectable quantity entering into the two gravitation reservoirs previously described. These will cover an area of 340 acres and will contain 1,249,000,000 gallons, with a top-water level of 166 feet and a maximum depth of about 38 feet of water. The total storage capacity of the six reservoirs on Enfield Chase would therefore amount to 2,640,000,000 gallons or 423,552,000 cubic feet. The execution of the tunnelled part would be throughout its length entirely in chalk (*producing a section and explaining the same to the Commissioners*) and being near to the upper surface of the chalk and overlaid with tertiary sands and intersecting the local disturbance already alluded to, as well as across the general dip of the chalk, no doubt a considerable quantity of water may be expected. It is assumed that from the tunnel works, with the additional seven square miles of gathering ground at its southern end, together with the Lea tributaries, it will secure a total daily yield of at least 47,000,000 gallons. The storage capacity necessary for securing a uniform daily flow has been ascertained at Feilde's weir to be 118 days for 66,000,000 gallons a day, and inasmuch as the volume is proportionably much larger and more constant from the upper tributaries, it is estimated that a provision of 90 days storage would be quite sufficient for the intended gathering ground. On the Rib it is proposed to adopt the plans designed by the late Mr. Rendel for a reservoir below Standon, which exceeds 200 acres, and would hold above 500,000,000 gallons, with a maximum depth of 20 feet of water, and below that again between Thundridge and West Mill a good site for a reservoir exists, as also above Watton, where strong drift clays are to be found in the valley of the Beane, between which two sites the necessary storage capacity for the remaining quantity may easily be obtained. Along the eastern side of the Rib reservoir it is proposed to make a catchment channel to receive the town drainage from a conduit to commence at Buntingford, and including on its course Aspenden, Braughing, and Standon, all of which now drain into the Rib and enters above the New River intake, the catchment channel will also take extreme freshes, and at its lower end by a tunnel 1,800 yards in length will divert the waters into the river Ash; the drainage of all these towns now comprise the principal population of the Rib area. Below, at West Mill the storage waters are proposed to be conveyed through a tunnel 3,000 yards in length to a point in the Beane valley a short distance below Stapleford, and joining at its lower end the diversion cut from the Beane itself, the united waters will pass by open channels and tunnels to the Mimram and thence to the Lea and terminating at the intended main tunnel mouth 2½ miles above Hertford. On the site of the proposed Rib reservoir numerous borings were made for the late Mr. Rendel to test the character of the soil, which showed variable loam and clay beds, and on the slopes and caps of the hills there are extensive beds of strong drift clays, from these conditions there can be little doubt as to making a sound reservoir. The reservoirs on Enfield Chase are all situated on a bare London clay surface, with drift gravels occurring at places on the margin of the upper or high level reservoirs. Considering that the locality is within 10 miles of London, few sites of a more favourable character could be found. Over the entire area of 610 acres only one residence and three farm homesteads of no great importance are interfered with, and residential damage to adjoining properties can hardly be said to exist. The character and extent in area and embankment of the largest of the two gravitation reservoirs of 210 acres assimilates closely to the one on the Brent near Willesden nine miles distant, which also stands on the London clay, and is 222 acres in extent, and has been in use for more than half a century as a supply to the Regent's canal. Besides the works contemplated for the diversion of the upper tributaries of the Lea it is intended to retain the New River channel for the flow of the Chadwell spring and to collect all the springs issuing from the west bank of the valley between Amwell and Rye House, and lift them by steam-power about 10 to 15 feet into the New River; also to purchase the water-rights of the copious springs which now work Hoddesdon Mill and to collect those and others in the locality, and lift them also from 15 to 20 feet into the New River. Those sources, it has already been stated, may be calculated upon to yield the respective quantities of 4,500,000, 6,000,000 and 8,000,000 gallons per day, and out of the gravels and sands near Hoddesdon where the water is assumed to absorb and soak away into the sands under the London clay, a quantity of at least 4,500,000 may be estimated and could be lifted into the New River at a height of not more than 20 feet. A very much larger quantity from this source might possibly be obtained, but perhaps only effectively by longitudinal adits or driftways up the sides of the valley, works which are not contemplated in the present scheme. The collective quantity of all these strictly spring waters could be secured at a very small cost and would amount in quantity in dry seasons to about 23,000,000 gallons per day, a volume equal to the present flow in the New River, and therefore, notwithstanding the proposed abandonment of all further abstraction of water out of the Lea at Ware, the New River would remain in its present condition as to volume as far down as Enfield, where further works are suggested. Until within the last few years the New River in its circuitous course at Enfield flowed over the site of the proposed embankment for the large gravitation reservoir at Enfield Chase, but recent works for the cutting off the bends now place the channel at about 1½ miles distant, and at the point of the lower junction of the old course the present river measures 13 miles from Ware, and at the level of 93 feet above Trinity, making a difference of head between the New River and the top-water of the intended reservoir of 37 feet. It is proposed that so much of the old course as would unite the intended reservoir and present river shall be reinstated, and lined and covered for a means of supply from the reservoir into the river; and considering that the water would come from a large mass, cool and clear, it is thought advisable and intended in the scheme to enlarge and arch over the New River throughout, from the 13-mile junction to Hornsey. With regard to the manner of distributing the total daily yield of 47,000,000 from the store reservoirs and 23,000,000 gallons from the New River, in all 70,000,000, there are various modes of division that might be made, but considering that two companies have to be provided for, it is suggested that the East London Company should have 30,000,000 delivered over 24 hours, from filter-beds placed at the foot of the high-level reservoirs, and pipes from thence to Stamford Hill, delivering at the level of 112 feet into a service reservoir. The East London Company have a small reservoir at Stamford Hill, and I propose by means of a large main to deliver there at the level of 112 feet, and from thence the distribution over the whole of the East London district would be by gravitation, except perhaps a small area immediately in the vicinity of Stamford Hill itself. 30,000,000 gallons would be delivered at 112 feet, and no pumping would be necessary over the East London district, excepting the most elevated part, at Stamford Hill, which is in fact surrounded by the pipes of the New River Company. The highest surface level of the populated part of the East London district is not more than 45 feet above high water-mark. To the New River Company the remaining 40,000,000 should be allotted, who in addition would have a reserve at all times of their new chalk wells at Ware, which are said to be of considerable importance. Beyond the quantity of 70,000,000 gallons, I should also mention that if the proposed new works of the East London Company are carried out, bringing 10,000,000 gallons from the Thames, that would at once raise the quantity proposed by this scheme to an available volume of 80,000,000, as it would only be

R. W. Mylne, Esq.

6 June 1867.

necessary when extreme dry seasons occur to pump the 10,000,000 gallons. You will bear in mind that the quantity I have taken is the average of the two driest years known for 20 years; at other times there is one-fourth more volume of water than the quantity that I have calculated on.

4996. (*Chairman.*) What is the absolute quantity that you realize from the two sources?—47,000,000 gallons and 23,000,000 gallons, 70,000,000 altogether, leaving the New River Company's chalk wells as a reserve to add to that on extreme dry seasons, I do not take those wells into account, the yield of which is given in evidence, at about 5,000,000 gallons per day.

4997. The present supply of the New River and East London Companies is 37,000,000 gallons, is it not?—The present abstraction from the river Lea is 37,500,000.

4998. And you bring it up to 70,000,000?—Yes, including the Chadwell springs. To continue the explanation of the scheme a large-sized main is proposed to be laid from the high level reservoirs along the new line of railway about to be constructed. I should mention that there is an intended new line of railway, from Wood Green to Hertford, and it would pass across one of the gravitation Reservoirs and be at such a level as would not be at all interfered with. It is further proposed to have a 48-inch main leading direct to the New River Company's filtering station at Hornsey, and on its course to supply by gravitation the districts of Enfield, Edmonton, and Tottenham, places now in want of an improved supply. A series of filter beds are provided, but I consider that the water would not require half the filtering than is at present necessary.

4999. I suppose that the filter beds are similar to those sand filters which are at present used?—Yes, they are similar in construction to the East London and New River sand filter beds. (*The witness described the line of main to the Commissioners upon the map.*)

5000. What is the distance from those reservoirs to Hornsey?—About 7,300 yards. The branch mains are shown and I include in the estimate large mains for Edmonton and Tottenham. The main to Hornsey under the head of 70 feet would be equal to deliver more than the whole of the New River Company's present daily supply, and for temporary purposes would enable the existing channel of the New River to be emptied and re-constructed from Enfield to Hornsey in brickwork in a sound and efficient manner. The engine establishment for lifting the water into the high level reservoirs would be placed at the upper end of the gravitation reservoir near to the intended new railway and station, where if hereafter a further quantity of water were required a large amount could probably be drawn from the chalk in that particular locality. The chalk there comes near to the surface. Thirty-six feet is the difference of level between the two sets of reservoirs, and the upper ones are all connected by culverts. From the description I have given it will be seen that the East London Company would receive by gravitation from the high level reservoirs a minimum filtered dry season volume of 30,000,000 gallons, and the New River Company 40,000,000 gallons direct from the storage reservoirs through filter beds to their present establishment. The upper tributaries of the Lea will be stored and drawn upon to produce the quantity nearly to their utmost in seasons of such extraordinary drought as occurred in the years 1863 and 1864, but a sufficient margin is left even at such a dry period for navigable and valley purposes, and within a short distance below the points of diversion springs and streams, with the rivers Ash and Stort, will augment the volume to the extent of their present flow. The advantages to the East London Company are that the water would be drawn from a purer source than at their present intake, being freed from the valley drainage and future cost of diverting it, and obtaining a gravitation supply in lieu of pumping, and the New River Company would have an increased and improved supply freeing them from the necessity for many years to come of looking to the river Thames or other distant sources, but confining their endeavours to within the legitimate and as yet unutilized valley waters of the River Lea.

5001. You have generally described your scheme by which I understand you provide about 70,000,000 gallons per diem?—Yes.

5002. Will you now state the cost of that scheme?—The cost of carrying out that scheme apart from the question of compensating by steam power such of the mills as would be affected by the abstraction, would be 1,250,000*l.*

5003. Does that cost include the purchase of land, easement, and severance?—Yes, it includes the purchase of land, easement, severance, and construction of works.

5004. Does it include the cost of the pumps and engine houses?—Yes, engine-houses, pumps, and everything.

5005. What would be the annual cost of engine power?—The cost of pumping at the engine stations at Enfield Chase to raise the water from the gravitation to the high level reservoirs, and at the Rye House district for lifting the collective springs into the New River will be 6500*l.* per annum inclusive of complete staff.

5006. Your scheme generally is a scheme which will double the supply of the New River and the East London Water Companies?—It will nearly double the quantity taken by those companies last year from the Lea.

5007. At an expense of 1,250,000*l.*?—Yes.

5008. That includes compensation, the purchase of land, easement, severance, and every question of that kind, and also the expense of erecting steam-engines, pumps, and all necessary machinery?—Yes.

5009. And of course it involves an annual charge for pumping?—Yes, and the pumping at present carried on by the East London Company would be wholly superseded, which recently has been given in evidence as representing in coal 6,000 tons per annum lifting 20,000,000 gallons per day to an average height of 112 feet above Trinity high-water mark.

5010. And this cost which you have described is to produce an additional quantity of 37,000,000 gallons?—An additional quantity of 28,000,000 gallons.

5011. Where you now supply 42,000,000 gallons you propose to supply 28,000,000 more gallons?—Yes.

5012. So that practically for London your scheme proposes to add 28,000,000 gallons at a cost of 1,250,000*l.*?—Yes; it adds 28,000,000 gallons, and the cost is to obtain that additional quantity and for works to convey the further quantity of 42,000,000 from higher points in the valley, and the collection of a large number of springs which now run into and mix with the Lea drainage; the whole 70,000,000 being conveyed in covered channels to London.

5013. And that is simply to bring the water and discharge it into the plant of the two companies; it includes no expense for distributing mains and so on, or for internal pumping for the purpose of equalizing the pressure in the district itself?—It includes no expense for distributing mains; that allotted to the New River Company would be delivered into their present establishment at Hornsey, where they would deal with it in any form they thought advisable; that to the East London Company would go direct into their mains, and their present pumping will be unnecessary.

5014. What is the character of the water generally?—The same character as the water now supplying the New River Company with the improvement of the diversion of the sewege of those towns on the rivers that have been specially mentioned; it would be of about the same degree of hardness. By impounding the freshes it would rather lessen the average hardness of the water.

5015. This scheme of yours would involve the necessity of some considerable outlay to divert the sewage and other things which find their way into those streams?—I do not suppose any works of diversion

above Hertford would be necessary particularly if the river is likely to be put under a new Conservancy Commission, with extensive powers to prevent pollution.

5016. (*Mr. Prestwich.*) If I understand you rightly, you would intercept the waters of the tributaries of the river Lea at a height of about 150 feet above Trinity high water?—No, it is from about 133 to 140 feet.

5017. How do you then get those waters into the reservoirs at 166 feet of height?—There is to be pumping from the gravitation reservoirs into the higher ones at 166 feet; the gravitation reservoirs are 130 feet with 3 feet of fall from the Lea into them.

5018. Do you propose to have any collecting reservoirs on the Lea and the Mimram?—No.

5019. Your scheme would be in fact diverting the present flow of those streams to a high level reservoir near London?—Yes, just so; and the scheme avoids the drainage of the river Stort and the Ash.

5020. By so doing would you not very materially interfere with the flow of the Lea below Hertford?—For mill purposes I should.

5021. You propose to take from those tributaries 40,000,000 gallons?—Yes, very nearly the whole in the very driest seasons.

5022. Should you take a uniform quantity from each of those tributaries?—In times of drought very nearly the whole would be taken. When the freshes come down they would pass on through the tunnel; on the river Rib the freshes would come down into the large reservoir proposed to be made below Standon.

5023. How many days' supply do you propose to provide for in all those reservoirs?—The total quantity of the six reservoirs on Enfield Chase is 2,640,000,000 gallons.

5024. That is sufficient for how many days' supply?—That would be 63 days' storage on Enfield Chase, with a further storage on the river Rib.

5025. What grounds have you for supposing that the streams which you intercept will at those points furnish that quantity?—From having gone carefully into the gaugings at Feilde's weir, which have been placed at my disposal, and from them forming an opinion on the proportional discharge.

5026. Of course a large portion of the water which passes Feilde's weir is received between the points where you intercept the water and Feilde's weir?—Yes.

5027. Are not there numerous springs which issue between Hertford and Feilde's weir?—Yes, and the rivers Stort and the Ash. Taking the quantity at 66,000,000 gallons at Feilde's weir from the gaugings, it is calculated, from various sources of information, that there will be 43,000,000 gallons collectable from the 246 square mile area, but assuming that the yield was taken on the proportion of the entire area due to Feilde's weir it would give 40,000,000 gallons.

5028. Have you any means of determining the quantity of water which issues in the form of springs between the point where you intercept the streams and Feilde's weir?—That is given in detail from the gaugings which are given in a Parliamentary report of Mr. Simpson and others, and from which those proportions are derived. One of the leading features of test is at the point of the New River intake, where the minimum flow under present conditions, without impounding, may be taken at 3,000 cubic feet per minute, or about 27,000,000 gallons per diem.

5029. Then in your scheme the actual gaugings the streams rather than rainfall is the important element, is it not?—Yes. I have based my calculations chiefly on Mr. Simpson's and other gaugings, all of which have been printed, and are given in the Parliamentary papers in the evidence of 1851 and 1852.

5030. The gravitation reservoirs which you propose to construct in Enfield Chase are to be upon the London clay?—Yes.

5031. Have you made borings in the clay to ascertain its depth at this point?—No, I have made no borings.

5032. In the upper part your reservoirs I see approach very closely upon the chalk, and upon the sands beneath the London clay?—Yes, the upper end of two of the high-level reservoirs.

5033. Would it be possible to construct reservoirs at that level with such a sub-stratum as that?—I think so. I have looked into that point very carefully, and where the embankments are placed the chalk is at a considerable depth from the surface, and the clay overlying is of some thickness.

5034. But the upper part of your reservoir touches upon the sand beneath the London clay?—It just touches it, and that part would be puddled; the extent of puddle would perhaps be of two or three acres.

5035. You propose to establish apparently some collecting reservoirs upon the Rib, above West Mill and below Buntingford?—Yes.

5036. What is the nature of the soil there?—I have carefully examined it. There were borings made some years since on the Rib, and I am of opinion that sound reservoirs can be formed, considering that the maximum depth of water will not be more than 20 feet.

5037. Is it not chiefly gravel overlying chalk?—No; there is very strong brick earth and loam of a thickness of from 6 to 7 feet, and in some places 10 feet, and the clay in my judgment will hold water.

5038. Is there not in that district a dark clay lying upon the tops of the hills?—Yes, but you are alluding to the Boulder clay, I suppose, which lies upon the tops of the hills.

5039. But the clay you refer to is found in the valley?—Yes, in a particular part of the valley.

5040. And this clay forms part of the drift of the valley?—It is separated from the clays on the top of the hills; it is wholly drift clay, forming strong brick earth.

5041. Is there any great thickness of that clay?—I have just mentioned that there is from 6 to 7 feet, and in many places 9 to 10 feet.

5042. Is it local?—It is continuous over that particular part where the reservoirs are proposed; it varies over the district very much.

5043. Is there any gravel above or below that clay?—I do not know of any extent of gravel except here and there there is a little gravel below it.

5044. When you pass through these 8 or 10 feet of clay, what do you reach?—Chiefly chalk.

5045. The total quantity which you propose to deliver from your several sources would be 70,000,000 gallons?—Yes.

5046. Notwithstanding that, you have just stated that the flow over the Feilde's weir does not exceed 66,000,000?—Yes.

5047. How do you account for the difference?—By impounding; by catching the freshes and collecting springs below.

5048. Of what period is that 66,000,000, the average?—66,000,000 is the average of the two driest years 1863 and 1864 at Feilde's weir, the lowest that has been known.

5049. Have you not calculated upon more than that average yearly?—No, I take that as the datum, and that being the average I can ascertain what storage room is necessary to give uniformly 66,000,000 all the year round.

5050. I understood you to say 70,000,000 all the year round?—I am afraid we are not alluding to the same point. At Feilde's weir the average yield of the Lea area in 1863 and 1864 was 66,000,000, and by storing the freshes it would give that volume. I have not gone into how much storage would be necessary there, as I do not propose to store at Feilde's weir, but to store at a higher point on the river where the proportion is 43,000,000 as against 66,000,000 of flow. The Ash and the Stort are left in their present condition, and are not included in the scheme.

5051. (*Mr. Harrison.*) This is a scheme which of

R. W. Mylne, Esq.

6 June 1867.

course could only be carried out by the existing water companies?—I presume so; the water rights belong to the existing companies.

5052. Have you submitted it at all to them, or is it now brought forward for the first time?—This is the first time it has been suggested. I only took the matter up recently in consequence of the evidence and report of the Pollution of Rivers Commission on the Lea, stating that there were no other areas where impounding gravitation reservoirs could be made on the London clay in the Lea basin, except below Broxbourne.

5053. Irrespective of the question of the mode of dealing with it, your knowledge of the Lea leads you to the conclusion that it is practicable by some means or other to obtain altogether between the two companies something like 70,000,000 gallons?—Yes, I consider so decidedly, which quantity would be a minimum on the driest years, and would be derived in part from a drainage area of 253 square miles, from tunnel interceptings, and from the collection of springs at Chadwell, Amwell, Rye House, and Hoddesdon.

5054. (*Mr. Prestwich.*) Is not the flow of water in the river Lea generally very uniform?—Yes, in the upper portions of the Lea it is even much more so in proportion per square mile than the flow at Feilde's weir.

The following Table of comparative supply was appended to the Waterworks District Map, exhibited by the witness:

North of the Thames.

NEW RIVER and EAST LONDON.

	1853.	1866.
Average daily supply in gallons -	30,135,753	42,277,769
Houses, manufactories, &c. - -	159,983*	204,939

* Including Hampstead.

CHELSEA, WEST MIDDLESEX, and GRAND JUNCTION.

	1853.	1866.
Average daily supply in gallons -	15,748,281	24,986,373
Houses, manufactories, &c. - -	65,152	90,302

South of the Thames.

SOUTHWARK AND VAUXHALL and LAMBETH.

	1853.	1866.
Average daily supply in gallons -	12,870,324	21,452,000
Houses, manufactories, &c. - -	66,787	111,183

Total average daily supply of the above seven waterworks companies 88,716,142 gallons.

The witness withdrew.

T. Hawksley, Esq.

THOMAS HAWKSLEY, Esq., further examined.

5055. (*Chairman.*) We have troubled you again in consequence of our instructions being somewhat limited when we had the pleasure of receiving your evidence on the previous occasion. Those instructions have now been so enlarged as to enable us to ask you some few questions with respect to the Thames basin generally, or rather the Thames watershed. When you were here before you gave us your opinion of the several schemes that have been suggested by Mr. Bateman, Mr. Hemans, and so on, can you now state generally whether there is capacity in the Thames watershed to supply a sufficient quantity of water for the metropolis?—I think so.

5056. You mentioned that the drainage area was 3,656 square miles, and the population 235·3 to the square mile?—Yes, including the rural population, that is the number very accurately taken out.

5057. You are aware, I presume, that the water companies have power to take 100,000,000 gallons per diem from the Thames, and that they are now taking but one moiety of that?—Yes, about that, rather under, I should think; on the average of the year probably not more than from 40,000,000 to 45,000,000 gallons.

5058. As an engineer well acquainted with the river, are you of opinion that they might take the maximum quantity which they are entitled to do, under their several Acts of Parliament, without injury to the river?—Yes, certainly.

5059. Without any interference with the navigation?—Yes, without any injury to the river at all. Below Teddington weir the river becomes tidal, and it receives consequently not precisely sea water, but the water that is thrown back by the sea, which is equivalent to receiving sea water, consequently it is not dependent upon the upland water entirely. Then again, it is necessary to bear in mind that the water is not lost to the Thames, it is only lost to a particular length of the Thames, it all comes in again at London, so that there is only the distance between Teddington and the metropolis in which the upland water is lost.

5060. Except that which is carried by the main culvert down to Barking?—I call that the metropolis. All will go down to Barking as a rule, during all the dry weather flow of the sewers, and consequently all the water taken from the Thames by the water companies will be carried down to Barking in the dry weather. There is no question that it all goes there, and therefore the intermediate part of the river is deprived not exactly of that quantity of water, but of a certain portion of it; that is to say, it occasions the run of the tide upwards to be longer, and the run of the tide downwards to be shorter in point of time, but the river itself flows up by this longer uprun of the tide practically to the same level, and if you were to reduce it to a matter of calculation you would not find it would make many inches difference, perhaps not more than two or three inches difference.

5061. So far as the river is concerned, up to Teddington, where the tidal influence ceases, you think that the abstraction of 100,000,000 gallons would not seriously interfere with the scour of the river below that point?—I do not think it would interfere at all with it; and for this reason, that the upland water of the Thames in its ordinary state has little or no influence upon the scour. In fact it is chiefly when in flood that it has an influence on the scour, and the floods of the Thames are so enormous that practically the quantity taken by the water companies then disappears from the calculation altogether. The maximum flood in the Thames is about 20,000,000,000 or 25,000,000,000 gallons in a day; that is a flood which occurs only once in a considerable number of years, not a very ordinary flood.

5062. What is the maximum height of the water line as raised by means of the floods?—I forget without reference; it is, I think, 10 or 12 feet.

5063. Mr. Simpson gave it as 10 feet 11 inches?—That may be; I do not know what Mr. Simpson's evidence has been.

5064. But in your judgment that would be likely?—Yes, that is very likely.

5065. Do you think that a larger quantity than the statutory limit might be taken from the Thames without any storing process?—Yes, I have no doubt about it.

5066. To what extent in your judgment?—I think that no sensible harm would be done either to the navigation or to the proprietors of the riparian property if that quantity were increased to double the statutory amount. If you took half the lowest volume of the Thames (and the lowest volume only lasts for a very short time) I do not believe that it would have any sensible influence.

5067. I understand that the lowest flow over that part of the river of which Mr. Simpson has taken careful sections, according to the gauging of the river

at that point, is 380,000,000 gallons?—My calculation is 360,000,000 gallons.

5068. Mr. Simpson stated that the average flow would be about 700,000,000 gallons, do you agree with that?—The average flow of three consecutive dry years is I believe about 6 inches of rainfall, and that would give nearly 900,000,000 gallons; that, of course, includes the floods of those years, although they are small; perhaps those Mr. Simpson threw out of the amount, it is I believe as nearly as possible 900,000,000 gallons on the average of those three consecutive dry years. I am giving summer and winter, and taking the whole year's flow. It is about 1,500,000,000 gallons on the average of all years. 5 inches run off in a very dry year, and about 10 inches on the average of all years.

5069. Are you of opinion that 150,000,000 gallons per diem might be abstracted from the river without injury to the river itself?—Yes, certainly, at the point where the companies take their supply—I do not mean in the tidal part—there you might take a much larger quantity without injury, but of course if you went higher up the river where there is no tide to fill up the void it would have a different effect. Supposing you went above Windsor, then of course it would very much diminish the flow of the Thames through Windsor Park, but it has very little effect below Teddington Lock, because the vacuity, or rather that which would be the vacuity if there were no tidal water, is filled up by the tide.

5070. Then the injury, if any, would simply be between Teddington Lock and the point where they take their supply?—Yes, but that is a pond, and therefore it would be of very little consequence.

5071. But supposing the demand of the metropolis exceeds say 150,000,000 gallons per diem, a larger quantity might be obtained from the Thames by impounding the storm water?—Yes, that must be taken with reference to the three consecutively dry years and not with reference to the average of the whole. You cannot deal with the average of the whole in any way, and therefore what you would have to do would be to impound the floods or a quantity equivalent to the floods of the years in which only 900,000,000 gallons was running past Teddington weir, instead of the floods of the wet years.

5072. But there are points in the Thames water shed that are peculiarly suited for the formation of a reservoir above Oxford, are there not?—They are very well situated as regards water tightness, being chiefly upon clay, but I believe there would be almost in any situation a considerable amount of excavation to be made and that is a most expensive process. We never like to make storage reservoirs by excavation. We always make them by embankments if possible.

5073. You mean excavation to get down into the clay?—Yes; to make a hole in the ground for the reception of the water is a very expensive process. To make it by embankments would be very much cheaper, but then you would spread the water out and perhaps rather overlap the clay in some cases, and you might, in that case get into more open strata, whether of the chalk or the oolites.

5074. Are you aware that the Thames Conservancy Board are now clothed with power to call upon all the local authorities on the banks of the river up to and including Oxford to divert their sewage and other polluting matter from finding its way into the river?—Yes.

5075. Of course the river would be greatly improved if that principle were adopted uniformily up the river?—The river would be very much improved near the towns themselves, but at considerable distances from the towns it would have no effect whatever, because all those matters are exceedingly decomposable in the presence of oxygen and become decomposed entirely by oxydisation. There is no such thing as a particle of fæcal matter put into the Thames at Oxford finding its way down to Hampton Court. It is all burnt up in fact by the combustion set up by the oxygen. There are three kinds of decomposition; there is the decomposition by oxydisation which is perfectly harmless, then everything becomes as sweet as it was in its original condition, because those animal matters are constituted of perfectly pure elements, and it is only the association which is unpleasant, and anything which disassociates the elements returns them to their original condition as pure as ever they were. The hydrogen which comes off from those matters after its liberation by the oxydisation is just as pure as it was in its original state, and so with regard to the other elements. As I was observing there are three conditions of decomposition. One is by oxydisation which is perfectly inoccuous and is a natural process of purification, the next is by putrefaction, which is excessively offensive, and then there is another species of decomposition by fermentation. When any of these sewage matters are put into running water which contains a vast amount of oxygen, as much as 40 or 50 gallons of oxygen in 1,000 gallons of water, it immediately attacks them and they become gradually decomposed and resolved into their original elements, or are re-associated in only perfectly pure states, nothing offensive remaining, and that has been going on ever since the creation of the world, the very Atlantic itself would ere this have been a cesspool if it were not for that process.

5076. What quantity of water, as compared with the volume of sewage, is necessary for the purpose of breaking up into its original elements the sewage which has been discharged into it?—Generally about 20 to 1. If the water flows rapidly and is very much disturbed, so as to be continually receiving fresh oxygen, a smaller quantity, even 12 to 1, will effect the process; if it proceeds very tardily it may take a little more; but usually 20 to 1 is perfectly abundant. I could give you very remarkable instances. Take Sheffield: nothing can be fouler probably than the state of the water at Sheffield, whereas if you go down to Doncaster the water is supplied by the waterworks and is actually drunk in the town. I do not, however, say that it is a desirable thing.

5077. How many miles is Doncaster below Sheffield?—About 20 miles.

5078. Is it a rapid running stream?—No, it is not rapid in summer. In point of fact it is controlled by the weirs set up for the navigation. But take the river Irwell leaving Manchester, receiving the Irk, the Matlock, and all the refuse of the manufacturing population for a great many miles; when it travels down only eight or nine miles to Warrington it is perfectly changed, it ceases, or nearly ceases, in that short distance to be an offensive river. I do not say that it has become all that it ought to be by any means, because the distance is not sufficient, and the flow is not rapid enough. The river is canalised, which prevents its flowing with all the rapidity it ought to have.

5079. You remember, do you not, the original condition of the river at Leicester after receiving all the sewage of the town into it?—Yes, perfectly well. I happened to be the engineer at Loughborough and also at Leicester. I made the waterworks at Leicester, and I advised the sewage works at Loughborough, and I also was called in to design waterworks for Loughborough, and I had on those occasions to take particular notice of the state of the river at all times, both at Leicester and at Loughborough, Loughborough being about 12 miles below Leicester. At Leicester the water was as black as this ink. I do not mean to say that it was absolutely so thick, but looking at it in a mass it was as black as ink,—nothing would live in it, and the smell was abominable,—but by the time it got to Loughborough it was entirely restored to its pristine condition. You could stand on the bridge there and see the fish swimming amongst the beautiful reedy and other plants growing in the water just as in the purest stream. You could see every pebble at the bottom. That is an instance of the effect of oxydisation.

5080. The water has symptoms of returning purity, has it not, within four miles of Leicester?—Yes, but not to the same extent as at Loughborough. The

T. Hawksley, Esq.

6 June 1867.

water was perceptibly impure at the driest period of the year down as far as Barrow. It could be just perceived there, but at Loughborough it was perfectly restored.

5081. Notwithstanding that law of nature, you would as a matter of prudence desire to have all sewage excluded from rivers, especially from rivers which are the source of supply of water for domestic purposes?—Yes. I would myself do a great deal to comply with the taste and even the prejudices of the people. I know, of course, there is nothing in all those startling statements that are made about disease travelling in water great distances and so on. I say there is no foundation for them in fact, but there are nevertheless strong and natural convictions on this subject which ought not to be disregarded.

5082. You are not able to speak as to whether disease in germ is carried from one point to another in water?—I am able to speak to it in this way. In the year 1848 or 1849 the cholera invaded the towns of what is called the Black Country, such as Bilston, Willenhall, Wolverhampton, Walsall, very frightfully, so much so that the people encamped out in the open air. I saw them myself. Those towns are all situated upon the river Tame, a very small river, which has its origin near Bilston; it flows down to Birmingham, a course of not many miles, tortuously perhaps twenty, but directly I suppose not more than a dozen. The water of that river was supplied to Birmingham, and yet there was not a case of cholera in Birmingham, excepting one, which was imported. Whilst in the adjacent city of Coventry, supplied by artesian and other springs, into which no sewage water entered, cholera was very rife and very fatal. I have been amongst cholera all my practical life. I believe I was concerned in building the very first large cholera hospital that was erected in England, in 1831. I have been amongst cholera abroad, when it has been in its worst phase, and I have been called in to almost every town in England where there has been any serious attack of cholera, because there has always been something to be done either with the water or the sewage, or something of that kind, and I can state most decidedly that this doctrine of the transmission of cholera and other diseases in the way that has been spoken of is utterly unfounded. Cholera is a very remarkable disease, and inscrutable as to its origin, but exceedingly rapidly propagated by infection, especially when the disease assumes an epidemic character. In 1853 or 1854 the cholera made an attack upon Newcastle, and it was very fatal there, but there was no cholera at Sunderland. Those two towns are about 12 miles apart in a direct line. Sunderland and Monkwearmouth are practically one town, just as Gateshead and Newcastle are another. There was no cholera at Sunderland excepting one or two imported cases, but on other occasions there had been a great amount of cholera at Sunderland, and on those occasions there had been comparatively little at Newcastle, although it had never been free. On that occasion (and I am speaking of towns that I have been connected with) after the cholera had done its work at Newcastle, it suddenly jumped over to Bishop's Auckland and settled down there, and was very destructive, then it passed down the river still omitting Sunderland, and returned upon Durham, but although those two places are upon the river Wear, Sunderland, which is also upon the river Wear below them, was never attacked. Take Copenhagen also as an example. The cholera twice visited the Baltic, without touching Copenhagen, although Copenhagen was then the worst sewered town perhaps in the world, all the night soil and garbage was thrown out on the little Island called Hamager adjacent to the town, and the stench from that island pervaded the whole city at night in hot weather. But in 1853 the cholera settled down there like a cloud, not attacking many other places in the Baltic, which it had visited before, and before I left more than 4,000 people had died. No change had occurred in the state of the city or of its water supply on the third visit of the cholera to the Baltic from the state which had prevailed on the first and second visitations. Then again to show that the water has nothing necessarily to do with it, cholera always follows a certain track, it has its origin in the East Indies, it travels usually through Russia sometimes for two or three years before it reaches England, and it passes always against the prevailing wind. The prevailing wind is westerly, but the cholera comes with the march of the Marmot from place to place almost directly in opposition to it. I am persuaded, and all my experience shows it, that those things to which it has become usual to refer it have nothing to do with the cholera, and that the cholera has nothing to do with them. The cholera germ is a thing of the imagination, inasmuch as nobody has seen it or has been able to watch its development or effects.

5083. Having regard to the capacity of the Thames watershed to yield a sufficient supply for the metropolis, (and when this system or purification is completed, whether for the sake of removing prejudice or any other purpose, to get rid of filth at all events the water must be improved,) you are of opinion that there is no necessity to seek a supply of water from a distance from the metropolis?—Certainly not. You have very fine water surrounding London in all directions, and it only wants utilising.

5084. You think that there is a sufficient quantity of water to supply the whole of the metropolis, independently of the New River, the East London and all the auxiliary aids which London has for water supply?—Yes, there is an immense basin and storehouse of water in the chalk, extending for miles around London, which might if hereafter necessary (it certainly is not necessary now) be resorted to.

5085. (*Mr. Harrison.*) You have been consulted, I daresay, by every water company in London?—I believe I have.

5086. For how many do you act directly as consulting engineer?—I have been engaged in all of the water inquiries from 1851 down to the present time. Occasionally I am called in professionally, but I have been consulted separately by a good many of them.

5087. In every individual case of a London Water Companies Bill, I dare say you have been consulted?—Yes, I dare say I have, or nearly so, except where they have gone merely for capital, I am not interested in that.

5088. Would you state your opinion as to what is the probable necessity per head of a population like London?—It does not exceed 25 gallons for all purposes.

5089.—Should you consider that taking 30 gallons was quite a safe calculation?—Yes, 30 gallons is a very wide calculation.

5090. That is rather below the present consumption of London?—No, I think the present consumption is 28 gallons. The calculations of the water companies are made very consistently, but they are calculated for engine purposes chiefly. They calculate usually by the displacement of the pumps, without making any allowance for the loss by valves and other causes. When we compare works of that kind with gravitation works, with which they frequently have to be compared, we take off from the pumping works about 10 per cent. to bring them to the level of gravitation works.

5091. Any calculations of the supply of London based upon 30 gallons per head for all purposes, would be an abundant and safe calculation?—Yes, more than enough.

5092. Looking forward to any alteration in the habits of the people which might induce them to consume more?—Yes, that takes all trades, all water-closets, stables, incidental causes of consumption, baths, and all household consumption and street watering.

5093. Assuming that reservoirs were made, and, as you say, you would not do them by excavation, it might be necessary, might it not, to bring the conducting conduits several miles higher up the river, to bring the water off and to fill those reservoirs in that

form ?—That might or might not be, it would depend upon the declivity of the particular watercourse.

5094. If it became necessary in after years to make any compensating reservoirs for the obstruction of a larger quantity of water, no difficulty would exist in finding a place or places upon the Thames to carry out such works ?—No certainly not.

5095. Do you consider that 200,000,000 gallons a day might be taken from above Teddington if you were ever called upon to supply that amount ?—Yes, I do.

5096. And that any question of possible damage might be met by such compensating reservoirs ?—Yes, certainly. I am not sure that even 200,000,000 gallons could not be taken without occasioning any sensible damage. Of course there would be a theoretical damage. You would have the lower waters running higher up than they do now ; I mean that by the operation of the tide the lower and the upper waters meet to fill up this cavity, and of course if you abstract from the upper waters, the lower waters will run so much higher up. But there will be a great improvement, and it is necessary to mention it, by what the Metropolitan Board of Works are doing. The training of the river through London will have an effect quite different from what many persons suppose ; it will have the effect of conducting the water up towards Teddington much more freely than it has been conducted heretofore, and it will really be an improvement. If the river be trained through London, about 750 feet wide, there will be so considerable a scour that its bed will be lowered, and there will be a very much larger quantity of water passing up than heretofore.

5097. (*Mr. Harrison.*) Looking at the largely increasing population on the banks of the Thames, unless some such provision had been made as that which was passed by the Act of last session giving power to the Thames Conservancy Board, in a short time the pollution of the Thames might have been such as to render all the water which we are taking from Hampton exceedingly bad ?—There is not a great population in the valley of the Thames ; above Hampton it is very small, and the town population, with the exception of Reading, is not sensibly increasing. Reading is not a large place ; it has under 30,000 inhabitants.

5098. I think you stated before your opinion as to the relative values of soft water and hard water ?—Yes ; soft water collected from the surface is very valuable in certain manufacturing districts, but in non-manufacturing districts chalk water is more valuable because it is much more agreeable. It is necessary while upon that subject to explain a matter which is very little understood, that is, with regard to the consumption of soap, upon which the errors of calculation are enormous. People suppose that all water used for detergent purposes is practically saturated with the soap, whereas it is not so as respects hard water. For washing in the morning, you take a gallon of water, half a gallon for washing the hands, and another half gallon afterwards for washing the face, you do not consume with the soap more than half a pint of water at each operation, indeed not so much as half a pint, for what you do is this ; you do not begin to make the whole quantity of water into a lather, you moisten your hands, take the water into your hand, and the soap upon it, and you rub it about till you get a lather, and you merely operate upon the quantity of water which is in your hands, then you rub it round, so as to take the dirt off your hands, and then you rinse your hands in the remainder of the water. That water is not saturated with the soap at all ; the soap has nothing to do with it, except that you use it for rinsing purposes, and you deal with your face in the same way ; and the washerwoman deals with her clothes in the same way ; she dips the clothes in the water, she takes them out, and rubs the soap on them, and then rubs the clothes together with her hands, and the small quantity of water that saturates the clothes is all that is dealt with by the soap, or nearly all ; but chemists and others who make grave calculations upon these subjects suppose the whole bulk of water to be saturated with the soap, and that is the great mistake they make. If you were to calculate the number of grains of salts acting upon the soap in the whole bulk of the water as they do, and suppose all that to operate upon the soap, to decompose it, you get to a vast calculation at once, the result of which is entirely fallacious : nevertheless of two waters equally good in other respects, I should select the softer. The improved supply to Paris has been brought from remote districts of the chalk formation expressly because, (1) it is salubrious ; (2) it is limpid ; (3) it is brisk. Whilst the softer waters flowing from the surface of the granite were rejected because they did not possess these properties in equal degree.

5099. (*Chairman.*) That is not the mode of calculation adopted by Mr. Bateman, is it ?—I am speaking of chemists and the great mistakes which are made in scientific books upon the subject of the saving of soap. The fact is, I am stating very much in excess the quantity when I say that a pint out of a gallon is saturated. You do not usually saturate anything like that amount of water with the soap.

5100. Your attention, as that of every other engineer, has been given to the question of constant supply ; do you consider it an important question for sanitary purposes that the poor people in all towns should have an abundant supply of water in whatever form it should be given ?—They should have an abundant and constant supply of water, but they ought to be prevented by proper means from wasting the water.

5101. Still you look upon it as an essential point that the poor people ought to have an abundant supply of water ?—No doubt ; but that is mainly a landlords question. I do not believe that there is any water company either in London or anywhere else that would not give a constant or unlimited supply of water if the landlords would only adopt those means for putting the fittings in proper order which are adopted in other towns where the constant supply is a success ; but if people perversely say, We will have the water constantly on, but we will not submit to proper supervision, and we will not bear the expense of proper apparatus, then it simply becomes impossible. And hitherto that has been the state of things in London.

5102. In many of the towns, I believe, where they have adopted the Health of Towns Act, have they not the power of shutting up houses that are considered to be in an unhealthy state ?—No, not unless they are in such a deplorable state that they are not fit for human habitation ; that is the expression in the Act.

5103. Would not the same words almost apply to a house which had no supply of water ?—No, because they may go somewhere else and get their water and carry it in. The house may be a very good house, as good as my house, and it would be quite fit for human habitation, and yet there might be no immediate water supply to it.

5104. Do you think that it would be an unfair thing upon the landlord to compel him to find the means of supplying water for his houses ?—I do not think it would be unfair. You are now speaking, of course, of houses below a certain rental, or houses which are let out in apartments to different tenants.

5105. Their being supplied with a sufficiency of water does not necessitate a constant supply night and day ?—No. A constant supply, with proper regulation and proper supervision, takes less water than an uncontrolled intermittent supply ; but then you must have that regulation and supervision, and if the public will not submit to the expense and will not submit to the inspection, nothing can be done for them ; but if the Legislature choose to empower the companies to make it compulsory upon the landlords, through some other authority, to put everything in a proper state of repair, and keep things in that proper state of repair, there is no reason at all why the constant supply should not be granted to-morrow. I do not think that there is any company in London that would think of resisting it ; but they are all in a state of alarm now, because

T. Hawksley, Esq.

6 June 1867.

they know perfectly well that if they were to turn on the constant supply to-morrow, probably three-fourths of the houses in London would receive no water. I should not get any water myself, it would all be draughted off into the lower districts, and run away in waste. But that is not so in the towns where there is a constant supply, and where those powers are conceded and where they are properly acted upon.

5106. I gather generally from your experience of this matter that you consider the Thames capable of supplying, taking it in connection with the Lea, any possible quantity that the population of London could require, and also that the quality of the water would be in your opinion unexceptionable?—Certainly.

5107. Therefore you would not consider necessary to go beyond that which you have at your own door for supplying this metropolis?—I should not.

5108. You also expressed an opinion, did you not, that if you had the choice of soft water or of chalk water you would hesitate in the selection which you would make?—I should not hesitate at all if I found as is almost invariably the case that the soft water were a tinted water, that is to say if it had any preceptible colouring of brown or yellow in it. All soft waters, or nearly all soft waters, are tinted unless they come from perfectly barren rocks or springs, and it is because of their power to take into solution such a vast amount of colouring matter, from the peat and heather, and mosses of various kinds in the neighbourhood where those waters proceed from, that they do practically always become tinted. Water of that kind would never be tolerated in London. That subject has been the cause of the most angry feelings and quarrels extending over many years and embittering man against man in a great many towns which I could mention, and particularly in Liverpool. Liverpool is in a manufacturing country, but it is not a manufacturing town, and the people of Liverpool delight in clear, bright, sparkling water, and do not value soft water that is tinted, and they will not have it if they can avoid it, whereas if you go to another town, a manufacturing town, such a place as Bolton for instance, amongst the bleachers or calico printers, or people of that kind, they would not have hard water, their trades and the wealth and comfort of the population are dependent upon the presence of soft water, there they would not have the water which pleases the Liverpool people, they go to the hills and bring in the softer brown water.

5109. (*Mr. Prestwich.*) Do you know whether there is not a difference of opinion even amongst dyers and calico printers with regard to the use of soft and moderately hard water?—I do not think that with regard to dyers and calico printers there is any difference of opinion, because the salts usually contained in hard waters affect and decompose some of their dye stuffs, and sometimes interfere with the brilliancy of the colours, and of course they are anxious to get water which contains as little as possible of those dissolved salts.

5110. There is greater economy, is there not, in the use of material where they have soft water?—It is not merely economy in the use of material, but it is because in calico printing for instance they want with respect to a good many colours to have very great brilliancy, it is in that respect that the French excel so much, their colours are very clear and brilliant. Some of the salts which are contained in many hard waters prevent that brilliancy of colours, and of course they are very anxious to avoid those waters.

5111. Do not some of the reds come out more brilliantly under the action of moderately hard waters?—Yes, that is as to some processes of dyeing. The rinsing process, for instance, after printing is one which they like to have performed with water that is entirely uncoloured, because a brown water stains the whites in cotton printing particularly. In cotton printing the cotton itself is capable of entering into a chemical union with the brown colouring matter contained in the water, and therefore, although it may not take a perceptible brown, the brilliancy of the white is destroyed, hence they want spring water as well as surface water. The calico printers use two waters, they use the water stored from the moors for their general purposes and then they try to get soft spring water, not hard spring water, but if possible soft spring water without colour, for finishing, as they call it.

5112. You are probably aware that some experiments were made in France at Lyons some years ago by Du Pasquier which give some very curious results with regard to the use of hard and soft water, showing in many cases the advantage of hard water?—Yes, but that is only in reference to a particular species of dyeing, particular colours that would be liable to be affected by the solvent property of soft water.

5113. With regard to the navigation of the Thames between Kew and Teddington I understand that the people on the lower parts of the river complain that they can no longer load their barges to the same extent that they could formerly. To what should you attribute that?—That is chiefly attributable to the removal of old London Bridge which operated as a dam and prevented the tide from receding as far out as it now does.

5114. But I understand that this complaint applied to a more recent period than that?—I should think that those complaints must arise from very vague observations and probably they are prejudices. I do not think it arises from the abstraction of water by the water companies, which is quite too small to produce any sensible effect. The river is very materially affected by the removal of old London Bridge The fall, if I recollect right, at old London Bridge was between 4 and 5 feet, and that of course always prevented the tide from receding as far as it recedes now. If the process of dredging and scouring goes on the effect of it will be that the river will be left comparatively dry at the upper end of the tidal range when the tide is out, and on the other hand the water will flow in much faster and will rise higher when the tide is in. You will have a greater variation at Teddington Lock say, or at Richmond, or any of those upper levels; the tide will rise higher and will fall lower.

5115. You would attribute nothing to the abstraction of the water?—Nothing sensible; nothing that they can found upon I am sure.

5116. Could you suggest any mode of meeting the requirements of supplying the poorer class of dwellings with a more constant supply of water without having the water delivered into each house or without having the supply constantly?—So far as regards houses which are in groups there is no difficulty because it is only necessary to have a sufficient cistern; one cistern would do for the whole; but with regard to houses not in groups and not supplied by one landlord, of course there must be a cistern to each house.

5117. Would you have the cistern underground?—No, the cistern should be at the highest point as a rule, not invariably so perhaps, but as a rule it should be at the highest part of the house.

5118. I am speaking of houses where one cistern would supply several houses, would you have that cistern underground with a pump by which they might draw the water, or above ground with a tap?—I should prefer having the cistern above ground, so that they could draw the water by a tap instead of by a pump, but it is not very material.

5119. Would not a tap be more liable to abuse, would not less water run to waste if a pump were used?—No, because where there is very little pressure it is easy so to arrange that the drawing cock shall close itself the moment the hand is taken off. There is no difficulty about that, but there is great difficulty where there is a heavy pressure and considerable power, because then the shock of the closing of this valve is apt to occasion a sort of aneurism in the pipe. It gradually swells out with each successive blow, and at last there comes a gap in it precisely the same as in the aneurism of an artery, and a repair is wanted which is a very undesirable thing. This objection may be to a considerable

extent removed by the use of the instrument called "the screw down cock."

5120. From your experience could you say which water keeps best in large reservoirs, soft or moderately hard water?—It depends entirely upon the quality of the salts which the water contains. Some hard waters produce vegetation with very great rapidity, and soft waters always produce vegetation with great rapidity. On the other hand there are hard waters which produce scarcely any vegetation. The waters from the oolites, such as those which are used at Cheltenham for instance, and are admitted there into a large brick reservoir, stand a year exposed to the atmosphere, and scarcely any vegetation forms at all. Chalk waters are very liable to form vegetation when exposed to the atmosphere. You see confervæ in them, a long stringy matter which they call the London silkweed will grow up in a few days. Water from the new red sandstone rock is still worse, in a very large reservoir it will become quite foul in about eight or 10 days. Waters containing carbonates produce plants freely, as a rule. Where there is an excess of carbonic acid the plants feed upon it, and if there happen to be present a few nitrates as well, vegetation then proceeds with uncommon rapidity.

The witness withdrew.

CHARLES GREAVES, Esq., examined.

5121. (*Col. Harness.*) You are the engineer to the East London Waterworks?—Yes.

5122. Are you engaged in any other official capacity?—I am not acting in any other capacity.

5123. Will you describe to the Commission the source of supply of your water company and how it is distributed?—The water upon which the East London Company are dependent for their supply is the river Lea, the sources of which are in the northern parts of Hertfordshire, and to some extent in Bedfordshire, and also in Essex. The lower part of the river is supplemented by springs of the watershed, partly in the county of Middlesex; the tributary rivers which are worth naming are generally considered six in number: the union of them takes place below Hertford and Ware, and from that point downwards the increase of the river is not very large. The East London Company take their supply from the whole body of the river in its lower part, but considerably above the reach of the tide, or any influences belonging to the tide.

5124. At what point do you take it?—The locality we have named is Higham Hill in the parish of Walthamstow; that is the best definition that we can give to it.

5125. How far does the tide flow up the Lea; not far above the docks, does it?—Yes, considerably above the docks.

5126. Is there not a dam or lock across there?—There are gates across one branch of the river, but at a certain point the river is divided into four or five millstreams, and the water goes up those millstreams, and so finds its way into the Hackney marshes, where the limit of the tide may be said to be. In fact, at the Ford, by Temple Mills, the city bound stones have stood for many years, and that was always considered to be the limit of the city jurisdiction on the Lea, as one of the tributaries of the Thames.

5127. How far from the mouth of the river does the tide flow?—I think it measures four miles, taking twists.

5128. How far above that is it that you take your supply?—About four miles above that.

5129. Have you only one point at which you take it?—We divert the course of the river into our works and take it as we require, and we let the surplus go by. These works, the most extensive in London, consist of a number of millstreams and reservoirs, which the company have had to put themselves in possession of. We are, as it were, becoming the owners of the whole river, and therefore we cannot be said to take it out of the river, as might be the case with some other works; we do not simply go to the edge of the river and take the quantity we want, but we appropriate the whole river.

5130. What quantity are you now taking out of the stream?—We are now delivering something under 20,000,000 gallons a day.

5131. What proportion is that of the stream which passes by you?—That will vary entirely with the season; during the year 1864 we took the whole of the volume; there was nothing went by, and we have had to plead poverty before the committee of the House of Commons, while arguing the necessity for going to the Thames to help ourselves with a supply from that river.

5132. From the river Lea you could not increase your supply, could you?—We shall be able to do so; I have a bill before Parliament now for increasing my reservoir room in the valley of the Lea, by which means I shall be able, having stored the water during the rainy seasons, to give a larger supply during seasons of drought, and I may be able to supplement my daily supply by the quantity which would be found by multiplying any given quantity, which you may choose to name, by any given number of days over which you may suppose the supply to be spread.

5133. Will you describe the scheme by which you propose to obtain a sufficient supply by storage in the valley of the Lea?—It is merely by the formation of reservoirs, partly by excavation and partly by embanking, in which the water will be impounded during the time when there is plenty.

5134. At what part of the valley is that?—Those reservoirs which will be in the parish of Walthamstow, in the lower part of the valley of the Lea, will not be dependent upon any one tributary alone, but upon the whole body of the river after receiving all its tributaries and its accretions.

5135. What is the size of the reservoirs which you propose to make?—I have at present 110 acres and I am going to have another 100 acres.

5136. With what depth of water?—The depth will be generally about 11 feet, but some parts will be deeper.

5137. What quantity of water will that store for you?—I expect to be able to store, when I have the whole storage in operation, about 500,000,000 gallons.

5138. For how many days supply?—5,000,000 gallons a day over 100 days we may say.

5139. (*Mr. Harrison.*) In dry seasons that would raise the quantity to 26,000,000?—Yes, according to any number of days that it is thought advisable to multiply by; it would give 5,000,000 gallons a day over 100 days.

5140. You are seeking power, are you not, under the bill which has now passed through the House of Commons to take 10,000,000 gallons from the Thames above Teddington?—Yes; that bill has passed the committee of the House of Commons and we have no reason to doubt that it will be granted by the House of Lords.

5141. They have put some restrictive clause into your bill, have they not, with reference to any future legislation?—They have not yet put it in, but the chairman said that the preamble of the bill was granted with the proviso that the committee should be at liberty to put into the bill anything which Parliament might determine this session.

5142. From your experience, what is a fair supply per head to calculate upon including every purpose?—The question has some range in it, because one district will have in it a much larger proportion of manufacturing works than another.

5143. Taking the population of London as a whole, what should you say?—I cannot see but what the

C. Greaves, Esq.

6 June 1867.

whole population of London ought to be very well satisfied with 24 gallons per head.

5144. You have made in your own district some special records upon the quantity actually consumed, have you not?—Yes, I have taken some pains to ascertain in special detail what was the proportion used in one place and another.

5145. Can you give the Commission the result of that?—I can give 15 cases of streets. One street averaged 306 gallons per house per day; the number of inhabitants I do not know; I have taken it per house. Those quantities were determined by the insertion of meters on the supply pipe of the street without any particular information or instruction to the people that they were being metered, but merely as a source of information for ourselves.

5146. What would you take as the average population of each house?—7½ I should think. No. 1 street comes out at 306 gallons per day; No. 2 at 329 gallons; No. 3 at 283 gallons; No. 4 at 132 gallons; No. 5 at 90 gallons; No. 6 at 96 gallons; No. 7 at 148 gallons; No. 8 at 45 gallons; No. 9 at 87 gallons; No. 10 at 194 gallons; No. 11 at 78 gallons; No. 12 at 358 gallons; No. 13 at 146 gallons; No. 14 at 73 gallons; and No. 15 at 37 gallons.

The witness delivered in the following table:

——	No. of Houses.	Duration of Experiment. No. of Years.	Gallons per House per Day.	——
No. 1	25	5½	306	45*l.* and taxes.
„ 2	37	5½	329	45*l.* do.
„ 3	35	5½	283	8*s.* 6*d.* a week.
„ 4	42	2	132	18*l.* and taxes.
„ 5	87	4½	90	22*l.* do.
„ 6	88	5½	96	10*s.* a week.
„ 7	92	5	148	23*l.*
„ 8	33	3	45	10*s.* a week.
„ 9	69	5	87	20*l.* and taxes.
„ 10	52	5½	194	35*l.* do.
„ 11	22	4	78	24*l.* do.
„ 12	47	5½	358	17*l.* do.
„ 13	41	5½	146	24*l.* do.
„ 14	18	5½	73	24*l.* do.
„ 15	28	5½	37	20*l.* do.

Average of the supplies per house per day 160 gallons.
Mean supply do. do. 168 „

5147. (*Chairman.*) I presume the houses are of different classes?—They are considerably different.

5148. And the average of 7½ would not apply all through?—I suppose it would not, but I should be loath to be precise; we find a great many people in the small houses. All but one of them are on the constant supply.

5149. (*Mr. Prestwich.*) How do you account for those differences?—Some of the houses are of a better class and have gardens. People are wilful and do not like being restricted, and they rather dare us to reduce the quantity, and they use the water in an unfair way. Some of those who have the least supplies are people who seem to be more amenable to reason in the discussion of the matter.

5150. (*Mr. Harrison.*) Have you reduced the calculation in any way to the rental of the houses?—There is an approximate valuation of each house in the table; some are in pounds per annum besides taxes, and others are in shillings per week.

5151. Are they generally houses of 20*l.* a year and upwards?—Yes, generally.

5152. Was that the daily supply?—That was the daily supply; it was calculated for seven days a week, because they were on the constant supply and consequently they had it on every day.

5153. (*Mr. Prestwich.*) There are two or three streets which show very largely in excess of the others, is there any particular cause for that difference?—No there is no abstract cause.

5154. Was any extra care taken during that time to see that there was no waste, or was it performed under the usual conditions?—You will see that it extends over a considerable period, a good many of them are for 5½ years, and during that time they were visited and examined and hunted up as to the waste, but in many cases we could not overcome their determination to use large quantities.

5155. (*Mr. Harrison.*) What head of water have you for your constant supply generally in the low districts?—The East London district is on a low level and rather uniform. I suppose the pressure may be considered to average 40 feet in general. It will run down to 25 at times, and at times it will rise to 50.

5156. In those cases in which you have had this constant supply so long in operation did you object to it?—Not at all. I myself am rather an advocate for a constant supply on the whole. Of course claiming to have the privilege of putting a reduced orifice somewhere on the pipe so as to prevent inordinate waste, I find no difficulty in giving a constant supply in my district. I have now 25,000 houses out of 92,000 who are continuously from years end to years end on the constant supply system.

5157. (*C. Harness.*) Will you explain what you mean by a reduced orifice?—Somewhere in the pipe between the pipe which belongs to the company and the cistern which belongs to the consumer, a disc with a small hole in it is inserted so as to prevent the water being drawn beyond a certain speed. That limits the draught of the system, and it saves us from inordinate loss which we know we should suffer, because notwithstanding that we have 25,000 tenants supplied in this way we cannot leave them unguarded, we are obliged to visit and inspect continuously over and over again.

5158. That limits the size of the supply pipe to the cistern?—Yes.

5159. (*Mr. Prestwich.*) What class of houses do you supply in this way?—We supply without distinction now.

5160. But does that include any of the poorer class of houses?—Yes, in fact ⅞ths, perhaps, $\frac{9}{10}$ths of all the houses that we are laying on now we are laying on upon the constant system.

5161. (*Col. Harness.*) And all upon that principle?—Yes, all upon that principle.

5162. (*Mr. Harrison.*) With regard to the poor people your experience would be, I presume, that it is of vital consequence to them to have a good supply of water?—Yes, it is. I advocate giving a complete and good supply to the poor on every possible ground, moral, social, and physical, with reference to the ordinary comforts of life. I think the absence of a proper supply of water to the poor is one of the grievances of the day.

5163. (*Col. Harness.*) When you do adopt that system and apply a contracted disc for the water to pass through you have of course to assume that you will allow them to have a certain supply in 24 hours?—Yes, certainly.

5164. What do you assume in that case?—I assume, say 180 gallons in 24 hours per house, that is the maximum, that is to say if they have no ball-cock nor any check upon it and they were to rob me to the utmost they could only take to the extent of 180 gallons a day. A pint a minute is 180 gallons a day.

5165. You calculate the size of your supply pipe by assuming that 180 gallons shall pass through it in 24 hours?—Yes, experience shows us that at the pressure of the district it will amount to 180 gallons, which is a very convenient datum to assume; the orifice is a small one, it is easily constructed, and it would have to vary with the pressure.

5166. (*Mr. Prestwich.*) Have you found that the constant supply to the poorer class of houses has led to any greater waste of water than under the intermittent supply?—I do not think it has.

5167. Has it not been apt to interfere with the works or with the taps and pipes, and so on?—There is a subordinate advantage which arises from

the use of the contracting ferule which delivers the water, that it certainly diminishes to a useful extent the pressure upon the ball-cocks. The pressure upon the tap and ball-cock where the pressure is very high is very apt to cut it out, and to make it wear and get out of order, and that is to some extent avoided by the contracted orifice through which the whole of the supply comes. There is no doubt that in towns where the constant supply is in practice, and where the pressure is very high the wear and tear of cocks is very great and the expense to the consumer is considerable in maintaining them in repair.

5168. (*Mr. Harrison.*) With regard to the quality of your water the analysis which has been made of it during the last month in the Registrar General report states this :—"The water supplied by the East London "Company from their reservoirs at Old Ford has "been specially examined for present sewage contami- "nation (that is sewage existing as such at the time "the analysis was made) but no such contamination "was detected"?—Yes, that is Dr. Frankland's analysis of the water for the month of May.

5169. Have you seen the report which has just been issued out from the River Pollution Commissioners?—Yes, I have.

5170. They recommend that the same course should be followed in the Lea as had been adopted by Act of Parliament with regard to the Thames, but giving power to a new body to prevent the pollution of the Lea for the future. If that were carried out do you think it would add to the good quality of your water?—I have not the least doubt that it would. I think that the report which the River Pollution Commissioners have issued is very well drawn, and that the conclusion that they have come to is the right conclusion. I do not see anything in it to quarrel with at all.

5171. Looking to the report based on Dr. Frankland's analysis—speaking of the water of Loch Katrine supplied to Glasgow—that water is stated to contain in every 100,000 tons three tons of foreign matter, and then comparing that with the East London water the East London water is stated to contain 27 tons of foreign matter per 100,000 tons?—Yes.

5172. Possibly a good deal of that foreign matter which is now found in your East London water would be done away with by the operation of what the River Pollution Commissioners suggest?—No, I think not much, because all the effect of any works such as the Pollution Commissioners propose would be the removal of organic matter, which is a very small portion of the whole of the contents. The difference between the total contents of the Loch Katrine water and the river Lea water arises out of the fact of the river Lea being moderately hard water, it is that which contributes to the hardness which is the great component of those tons of foreign matter.

5173. As regards that you think it would make no alteration in it?—Not much.

5174. Is Dr. Frankland appointed officially by any Government office to make those reports?—I really am not able to answer that question, but as the Registrar General and Dr. Frankland seem quite to understand one another in the matter I presume Dr. Frankland is paid by the Home Office in some way. He has a remuneration for his analyses I believe; but I do know this that Dr. Dundas Thompson who carried on those analyses for many years received the very smallest possible pittance for the trouble which he took in doing it.

5175. Do you consider it desirable that some official person should make such reports regularly monthly of all the waters?—I think it is a very satisfactory thing that it is done through some Government department so as to be above any kind of suspicion.

5176. As being to the water companies satisfactory as well as to that of the public?—Yes; both to the companies and to the public certainly.

5177. You have of course had your attention directed a great deal to the river Lea, and although you have gone this session to Parliament to obtain a large quantity from the Thames above Teddington, yet do you consider the resources of the Lea to be now exhausted by your two companies, the New River and the East London taking water from it, I mean independent of the question of the cost of getting it, but taking it as a purely physical question?—I am of opinion that as the larger portion of London is dependent upon the Lea it ought not to continue any longer dependent upon the Lea alone for its supply of water as to quantity. The caution that we had from the drought of 1864 was convincing. There is no room to doubt the question any longer.

5178. In the case of the New River their engineer has stated that he believes it is quite capable of yielding 10,000,000 gallons to each of the companies in addition to the present quantity by proper storage reservoirs, do you concur in that view?—I am not inclined to store so largely or to depend upon storage to that extent, because I know that there are winters when it is quite likely those reservoirs might not be filled. The winter of 1858 went off without a single flood; we have charge of the flood-gates ourselves on the river at Lea Bridge which govern the whole flow, and in the winter of 1858 we did not draw a single gate; therefore where would the reservoirs be filled from in such a season?

5179. I gather that your view would be that you would prefer going to the Thames proper for any additional supply, leaving the Lea to be applied to in case of necessity some 100 years hence?—I am going to make a 100 acre reservoir now upon the Lea in addition to what I have got. I shall combine my Thames works and my Lea works together, and if I cannot fill my Lea works with the Lea water I shall fill them with the Thames water. I should not rely on the Lea alone or on the Thames alone, but I should allow my reservoir in the Lea to be filled from the Thames when necessary. I consider the Lea alone not to be depended on even for the East London, and less so supposing the New River Company do an equal amount of work.

5180. Have you a thorough knowledge of the whole of the Thames basin?—Pretty well, but not so intimately as I have of the Lea.

5181. You heard the evidence which was given just now by Mr. Hawksley?—Yes.

5182. Do you agree generally in the views which he expressed?—No, I cannot say that I do. I do not think these rivers are going to last so long as Mr. Hawksley does. I think it is necessary to be cautious in time. I would not like speculating upon any one of those rivers round London lasting for the next half century; not only the Lea or the Thames, but other rivers; I mean lasting as a source of water supply independent of any foreign aid.

5183. You calculate that you may have to go beyond the Thames basin for the supply of London?—I think it is quite a fair thing in prospect to talk about. I do not think there is anything foolish in the view that it may be necessary to go beyond the Thames basin; that is to say, you will either have to do that or to store very largely, more largely than anyone has entered into the practical estimation of.

5184. Should you agree with Mr. Hawksley in his opinion that you might take 150,000,000 gallons daily, without the necessity of storage?—I should hardly like to commit myself to that opinion, because we do not know yet the complete effect of the removal of sewage from the Thames by the main drainage works; we do not know whether future droughts may not be more trying and disastrous to the river than the droughts which we have had experience of. The drought of 1864 surpassed anything that anyone knew of at all; we have no records anywhere of the loss of water going on to such an extent as took place in that season. It is known by gauging and special observations that we lost quite 13 inches of water by evaporation from enclosed reservoirs during the summer months of that year.

C. Greaves, Esq.

6 June 1867.

5185. Do you incline to the opinion that it is necessary at this time of day to look to other sources of supply than the Thames?—I think it is taking the subject quite early enough to talk about it, but I do not think the time is come for going beyond the Thames.

5186. (*Col. Harness.*) Do you mean that 13 inches were lost in the depth of the reservoirs?—Yes, I mean 13 inches in depth of water.

3187. (*Mr. Harrison.*) You do not put any number of years to come as the probable time?—There are so many things to be considered that I hardly think it is worth while entering into any definite estimate of years. We are told by Professor Glaisher that the temperature of the country is increasing, that we have an average rise of one degree. These things affect the question of evaporation immensely. It is a scientific point which is not at all sufficiently understood, that four-fifths of all the rain which falls from heaven is re-evaporated from the earth. We have rain-gauges all over the kingdom by means of which we should have no trouble at all in measuring the quantity of rain that falls, but it seems very few people can be found to take any trouble to measure the quantity of water that is re-evaporated. If we have an average rainfall of 25 inches, and during any considerable period of successive years, 20 inches of water is re-vaporated in the same time, you have only five inches of water to deal with, and that five inches is the result of the temperature and climate of the country, but if that temperature increased the five inches would be diminished, and we find that this really does take place in the hot years, particularly when two or three hot years came in succession.

5188. (*Mr. Prestwich.*) You have probably observed that the Lea water would hardly be affected by the introduction of the present system of drainage of agricultural lands, but do you think that it is likely to affect the flow of our larger rivers?—There seems to be a general idea that the discharge of the river waters is quicker than it used to be.

5189. Especially when it passes through clay lands?—Yes.

5190. The Lea, coming from a chalk district, would hardly feel the effect of that?—I do not know that the conclusion is altogether certain, that such is the effect I agree with Mr. Bailey Denton, to a certain extent, that under-drainage carries a great deal of water down into the soil, in fact the whole philosophy of draining as a method of raising the temperature consists in that point that a great deal of water is carried from the surface down into the under drains and pervades the soil before it reaches the under drains and is not shed off or evaporated from the actual surface as is the case in an ill-drained country. The enlargement of the main carriers certainly quickens the delivery of the water off the district, but the modern process of under draining may not do that.

5191. But it would affect in some way or other the flow of water in the river either to spread it over a greater extent of time or to make the flow more rapid?—There seems to be a general opinion that the discharge of rivers is affected by drainage and quickened.

5192. And that is a process which is now going on to an increasing extent?—Yes.

5193. But in a river like that from which you draw your supply passing through a chalk area where springs flow with great regularity, it can hardly be affected by such a cause as that?—No, so far as it is dependent on those springs.

5194. With regard to the future supply to London, do you think that at any time the springs in the chalk below London might be rendered available for the supplies of the districts east of London?—I do not think that there are any springs in the chalk to any great extent on the east of London.

5195. You are acquainted with the springs at Grays, I presume?—Yes.

5196. We have been given to understand that they could deliver and have been proved to deliver 10,000,000 gallons of water a day?—I understand that that delivery is claimed by parties interested, but the water in the chalk there, if indeed it can be called a spring, is at a very low level, at a level no higher than the Thames, and therefore the sources of that water to my mind are rather uncertain.

5197. That quantity has been determined by pumping, has it not?—Yes, there have been a series of excavations in the chalk there, but no passage of water takes place at all without pumping.

5198. But do you not consider that the circumstance of their having pumped three days in succession and obtained that quantity shows that the springs are of considerable power?—I have no doubt that there are springs, but the extent of which the water may be drawn upon is a difficult point to determine. I am not inclined to think that they can be depended upon to the extent which is claimed for them.

5199. At present the limit of their supply I believe is at Brentwood and Romford?—The water supplied from there is but small; I have been acquainted with the springs for years; they were offered to our company before the present company entered into the speculation, and I examined them repeatedly before anything was done in the way of forming them into a water company for supply, and if I had seen a natural continuous flow, or any indication that the water was discharging itself at low-water mark into the river, or in any other way, I should have looked upon them with a different eye.

5200. I presume that the overflow from those springs would find its way to the river nearly at low water?—Yes; but I walked the whole of the low-water line of the river but I never could see any trace of any water coming out. I went especially to find out that particular point, because if I had found water issuing even at low-water mark I should have concluded that there was a certainty of the springs being powerful.

5201. Coming through the gravel it would be dispersed over a very large surface and would not show much at any one point?—Quite so; but I think where such springs are known to exist they do flow, and you see an indication of them somewhere above low-water mark in the mud, or the silt deposit.

5202. (*Mr. Harrison.*) Is there any other point which you could suggest of interest to this Commission, knowing as you do the subject of their inquiry?—I hardly know whether there is or not. I have been before so many boards of inquiry lately that I am exhausted upon almost every subject. I have had to tabulate and to summarize almost every matter connected with the affairs of the river Lea and my company in every shape and way. I have some papers here which I can hand in with regard to the constant supply of poor courts. We have found lately the advantage of putting up an aparatus for supplying courts with a cistern; not an apparatus which is charged direct from the main but with an arrangement of drawing-taps, made so that the charging and the drawing cannot take place at the same moment. The cock is what we call technically a three-way cock. When you draw from the vessel you shut the connexion with the main, and when you release the handle by which you draw, it charges itself again from the main immediately of its own accord.

5203. (*Chairman.*) Without moving it again you can only draw a certain quantity?—That is so.

5204. How much do you allow them to draw with one movement?—About a gallon or a gallon and a quarter. We find that mode of construction acts very well, two or three charges will fill a pail. The machine is made of cast-iron, and there is nothing about it that can be stolen; it is fastened to the wall, and the people enjoy the advantage of the water being fresh. I have in my hand a list of places where we have put them up, with the number of houses dependent upon each apparatus.

The witness delivered in the following table:

WASTE PREVENTERS.

Where fixed and the number of houses on each, 21st May 1867.

Situation.	No. of Houses.
Angel Alley, High Street, Whitechapel	6
Ann's Place, Boundary Street	8
Bud's Cottages, Portman's Place, Mile End	5
Charlotte Place, Turoit Street, Charlders	5
Crown Court, Wentworth Street	14
Caroline Place, Whitechapel	12
Diamond Court, Great Pearl Street	7
Dalston Square, Nelson Street	6
Dinah's Buildings, Cox's Square	12
Duncan Court, Boundary Street	12
E. L. W. W. Co. Cottages, Horsepond, Stratford	4
George Court, Harriss Court	14
Gibraltar Gardens, No. 1 } Do. No. 2 }	32
Hewett's Court, Jubilee Street	7
Hobson's Place, Pelham Street	14
Hobson's Court, Mile End New Town	15
Hank's Court, Poplar	10
Inkhorn Court	9
John's Place, Hunt Street	14
Jones Buildings, Gower's Walk	27
Neatsby's Court, Fashion Street	3

(*Witness.*) I have also a table showing the per-centage of the houses on constant supply which I find has gone on increasing from four up to 28 per cent. These are probably all on the principle of a contracted orifice.

The witness delivered in the following table:

PER-CENTAGE OF CONSTANTS.

1854	66,191	2,898	4·37
1855	68,053	4,134	6·07
1856	69,876	5,299	7·58
1857	70,938	6,000	8·45
1858	72,442	7,056	9·74
1859	74,201	9,000	12·12
1860	76,310	11,000	14·41
1861	77,944	12,712	16·30
1862	79,748	15,140	18·98
1863	82,556	18,000	21·80
1864	84,564	20,000	23·65
1865	87,278	22,497	25·77
1166	88,945	25,305	28·45

5205. (*Mr. Prestwich*) Then you avoid any difficulty from excessive waste?—Yes; which is always the argument against the constant supply system. I can also furnish the Commission with some other figures. In addition to the experiment carried on on a large scale, covering the whole supply of the district by large meters. I can give an instance of a district including 9,031 houses. It did not affect the rents or the pecuniary arrangements between the company and the people, and I find that out of the 9,031 houses those on the constant supply amount to 73 per cent., the remainder are on the intermittent supply. The water taken by the houses on the constant supply is 118 gallons per house per day for seven days.

2506. (*Mr. Harrison.*) Taking them at five to a house, which would be a very small number that would give 24 gallons per head?—They are not stinted and there is no complaint. The district is wholesale under the constant supply, and that is the result as a matter of experiment.

5207. Would that include water for sewage and everything?—No, not at all; first of all the gross supply is taken out, as given to the district—from that is deducted all that is supplied by meters to manufactories, the road watering as supplied by meter, and every kind of trade and manufacturing, and the remainder is the domestic supply proper, which when divided by the number of domestic tenants gives 118 gallons per house per day for seven days a week.

5208. Captain Tyler has taken for your district 7½ gallons per head, has he not?—I gave him the figure correctly, and as computed from the census it comes out 7·3 gallons. I take the whole of the district from the census of 1861, the number of inhabited houses and the population; there can be no better way of getting at it.

5209. In round numbers you may take it to be about 15 gallons per head?—Yes, for domestic use exclusively.

5210. (*Mr. Prestwich.*) Do you use the same water for domestic purposes and for watering the streets?—The company are prohibited from trading in any other water; they are bound to filter all their water; they have no exceptional clause entitling them to use any second-rate water; and therefore the same quality of water is used for whatever purposes it may be required.

5211. Do you think it would be desirable to separate the water required for domestic purposes from that required for flushing the sewers?—The cost of filtering is not so very great, and it is better to filter it all; it might be an advantage to escape the cost of filtering on a certain quantity, but it would lead to uncertainty; because then the people might be buying second-rate water from the company under the guise of trade and using it for culinary and domestic purposes, which would be contrary to the intention of the Legislature.

The witness withdrew.

Adjourned to Thursday the 20th of June at 11 o'clock.

Thursday, 20th June 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

J. Firth, Esq.
20 June 1867.

JOSIAH FIRTH, Esq., examined.

5212. (*Chairman.*) You are a member of the firm of Firth and Company, at Heckmondwyke, Yorkshire?—Yes, of the firm of Edwin Firth and Sons.

5213. You are a cloth manufacturer, are you not?—I am a manufacturer of carpets and blankets, and of cloths also.

5214. Have you been long a manufacturer of woollen goods?—I have been connected with it about 15 years.

5215. And do you take an active part in the manufacture or in the sale?—Both in the sale and in the manufacture.

5216. Do you manufacture flannel goods?—Yes, blankets and woollen cloths for army purposes chiefly.

5217. Is that a cloth requiring a great deal of scouring?—Yes.

5218. You have to wash out the soap?—Yes.

5219. (*Sir B. Phillips.*) Do you buy the yarn or spin it?—We spin the yarn and manufacture it from the wool itself.

5220. (*Chairman.*) You use a large quantity of soap, do you not, in order to get out the grease?—Yes.

5221. And necessarily a large quantity of water?—Yes.

5222. What class of water are you supplied with now?—The water that we have chiefly is from a colliery that we used to work, and that water is rather hard.

5223. Have you constituted that colliery a well?—Yes, we have constituted it a well, and we pump the water from the old works. The water is rather hard for dyeing purposes, and also for scouring purposes; it is not so good as soft water for such purposes as those.

5224. Can you tell us the degree of hardness of that water?—No, I cannot tell you that. We have also a supply of water from the town waterworks which is soft water, and very good water.

5225. And do you use that in preference to the water which you yourself possess?—Yes, for certain colours we use it. We are almost obliged to use it for the dyeing of certain colours, and we should use it for everything if we could get the requisite quantity at a reasonable price, except for black, blue, and magenta, for which colours our own water is the best.

5226. Is there great economy in the use of soft water as compared with hard?—For certain purposes of our manufacture it would be so.

5227. For what purposes?—For scouring and dyeing certain colours; for all colours I may say it is an advantage.

5228. What colours are developed better by soft water?—More particularly the lighter colours, scarlets and crimsons. It is almost indispensable for dyeing scarlet, and also for the washing out of scarlet it is very necessary to have soft water, or at all events water that is not impregnated with chemical properties which would injuriously affect the colours in any way.

5229. Do you find that you are able to use the water which you pump from the old coal shaft for dyeing purposes?—Not to the same advantage as the town's water, which is soft.

5230. You find it not so good for the development of colours or for scouring purposes?—Certainly not.

5231. Do you know the relative value of the water in an economical point of view?—No, that is a thing which we have not tested; except for scouring yarns, where we find by using the towns' water we effect a saving of 25 per cent. of the quantity of soap used for this purpose.

5232. Have you observed at all the consumption of soap in using the water which you pump from the coal shaft as compared with the amount of soap used with water which is of a soft character?—I may say that the supply from the waterworks is not sufficient for our use in our works, we are obliged to confine ourselves to our own water, except for certain colours.

5233. I understand you to state that for the purposes of developing certain colours, and especially light colours, scarlet and others, and also for scouring purposes, soft water is very much preferred by you?—Yes.

5234. I ask you if you can give any reason why you prefer it, or if you can give any reason as to the comparative consumption of soap by the one system or the other?—We have not tested the relative cheapness of the waters as regards their scouring properties, except, as before said, in the case of yarn scouring.

5235. Are not manufacturers generally, especially Yorkshire manufacturers, quite alive to that consideration?—The fact is that we have not the necessary quantity of soft water to make use of. We are quite aware of the fact that it has a decided advantage over hard water, but not having a soft water we are obliged to content ourselves with the hard water in our well.

5236. Is that from the insufficiency of supply, or is it because of the cost?—From the insufficiency of supply.

5237. What quantity of soft water are you taking for your manufacturing purposes from the water company?—We should use more if we could get it, at present we average about 2,700,000 gallons yearly, and the price is 6*d.* per 1,000 gallons.

5238. What the Commission desire to know is, in the first place, the class of water that you are using, and if soft, why you are using soft water, and what are the economic advantages in the use of soft as compared with hard water for manufacturing purposes, and especially the class of manufactures such as is carried on by your firm?—I can merely give our general experience that soft water has a considerable advantage over hard water. We have not had a sufficient supply of soft water, and cannot get it, no matter what the price is at present. If we had a supply of soft water offered to us for certain purposes we should use it whatever the cost was. For other purposes we should then have to estimate the difference in value between the hard and the soft waters, independent upon the price of the soft water as compared with the hard. If the price was equal for all purposes we should undoubtedly give the preference to soft water.

5239. (*Col. Harness.*) Are you now taking all the water that the company will give you, or are you only taking such a quantity as you think fit to pay for?—We cannot take the whole that we require, nor can we apply it to the purposes which we should do, because we cannot depend upon it, and it would not pay us to lay down pipes and everything of that sort unless we could depend upon a regular supply.

5240. Then the supply is uncertain?—Yes, the supply is uncertain.

5241. What do the company charge for the water?—Sixpence per 1,000 gallons.

5242. What do you think the water which you get from your own well costs you?—We think that it costs us about one half of that; it costs us quite half, because we are obliged to pump the whole of the water out on account of its being an old colliery; the water is affected by the old works, and therefore we are obliged to pump the whole of the water in order to keep it clean, to keep it clear from canker.

5243. (*Chairman.*) Are you obliged to keep the pump constantly going?—Yes, day and night.

5244. Have you any iron in that water?—Yes.

5245. That is an objection, is it not?—Yes, for everything except the dyeing of black, blue, and magenta, for which it is an advantage.

5246. (*Sir B. Phillips.*) Do you mean that it is an objection for dyeing purposes?—Yes, and for scouring purposes also, except as aforesaid.

5247. You state that you prefer soft water to hard water; do you also state that if you could get a sufficient quantity of soft water at any price you would take it in preference to the other?—For some colours we should.

5248. Do you find an advantage in the use of soft water in the brilliancy of the colour that is produced?—Yes.

5249. Have you an advantage in the return in weight?—Yes, and in the brilliancy and clearness of the colour.

5250. How is it with regard to the dark colours?—In dark colours, such as black, it is not of the same importance.

5251. Do you scour your yarn before you dye?—Yes.

5252. Do you never scour anything after it is woven or dyed in the piece?—Yes.

5253. I suppose you dye your scarlets in the piece?—Yes.

5254. Do you find that you get a brighter colour from soft water than you do from hard in scarlets?—Yes.

5255. Do you ever scour your yarns first, and then dye them, and then weave them?—We do for carpets; in that case the yarns are always scoured first.

5256. As a rule, you find that you get a better colour from soft water than you do from hard water?—Yes; that is to say, we find it so with regard to light colours.

5257. What are the advantages, irrespective of colour, in the use of soft water as compared with hard water?—We find that it scours and otherwise cleanses the yarns, or cleanses the pieces with very much less soap, and better than the hard water does, but at the same time I am not prepared to say what the difference is. We have not tested that, because there was really no necessity for it; we have no soft water to use.

5258. Supposing that soft water cost you 6*d.* per 1,000 gallons, and that hard water cost you 3*d.* per 1,000; taking into consideration the difference in the brilliancy of the colour, and the difference in the quantity of soap which you would require in the use of soft water as compared with hard water, do you think that soft water would be cheaper for your manufacturing purposes as a whole than hard water?—As a whole I think it would, because some of the things which we manufacture are blankets, which we dye in the piece. With regard to anything that is dark in colour, such as grey blankets, or black, or brown, or any dark colour of that character, I should consider that hard water would not be objectionable for either dyeing or for washing off, but of course it would be in the cleansing.

5259. (*Chairman.*) Do you ever dye blankets?—Yes, we dye a great many blankets for foreign markets; they are not of much use in the English market.

5260. Are they dyed in order to save washing?—I do not know.

5261. (*Sir B. Phillips.*) In dyeing those blankets, does the soft water improve the texture?—I should think it would.

5262. (*Mr. Harrison.*) What water do you use for household purposes?—We use the soft water.

5263. Do you use it from choice, or from expediency?—From choice, decidedly.

5264. Do you prefer drinking soft water to hard?—Yes, decidedly; we prefer for drinking purposes soft water to hard water as a matter of taste.

5265. (*Chairman.*) How many hands do you employ?—About 1,700, averaged, but sometimes I daresay we double this, in fact I may safely say we have tripled it.

5266. Do the people use the soft water in their houses?—Yes, certainly, so far as we are acquainted with their houses. We have a great number of our own houses, and we have had the towns' water put into those houses.

5267. Generally speaking, if you had a choice you would prefer, would you not, soft water for all the purposes of your manufacture?—Certainly.

5268. And you believe that economy would be consulted by the use of it in preference to hard?—Yes, even if it were at the same price.

5269. But you are not prepared to tell us to what extent would be your saving by the use of soft instead of hard water?—I am not prepared to say that.

5270. From what you have observed as a practical man, in scouring and in getting rid of grease and other matters which you have to scour out either of yarn or of manufactured goods, those things appear to be removed with greater rapidity and with the consumption of less soap by the use of soft water than by hard?—Yes, I may say that we have tested it in our case; in the scouring of yarns and saving of soap from the use of soft water over hard would be about 25 per cent.

5271. (*Sir B. Phillips.*) What amount of soap do you use annually?—I cannot say that off hand. Our production varies very much, and therefore the use of soap varies.

5272. (*Mr Harrison.*) But your consumption of soap must be exceedingly large, must it not?—Yes.

5273. (*Mr. Prestwich.*) What is the source of supply for the town water?—We can connect with the Dewsbury, Batley, and Heckmondwike Waterworks, and they get the water from Dunford Bridge near Penistone, between Penistone and Sheffield, from the river Don.

5274. Do you know the hardness of the water which is supplied by the town?—That is soft water.

5275. I presume you mean that it is more or less soft, but it would still show a certain amount of hardness whether it were 1, 2, or 3 degrees?—I should think it would be a few degrees of hardness, but I cannot say exactly what.

5276. Can you tell us the degrees of hardness of the water from the well?—No.

5277. Has the well water ever been analysed?—No, but the town's water has been analysed, I believe.

5278. Could you furnish us with that analysis?—I am not able to do so; I am informed that it is the next water to the Whitehaven for purity, which is one of the very purest waters, and that it is about 3 degrees of hardness.

5279. You state do you not, that the water in the well contains iron?—Yes, there are iron beds there in connexion with the coal.

5280. That of itself would render the water objectionable for manufacturing purposes?—Yes, to some extent it is an objection.

5281. Therefore you could not tell us, supposing the water were free from the iron, whether the presence of any other ingredient causing the water to be hard, such as carbonate of lime, would or would not be objectionable?—It certainly would.

5282. You have stated clearly that the use of hard water is objectionable on the score of economy, and that there is a saving in the consumption of soap between the use of soft as compared with hard water, and with regard to colours you state that for certain purposes you prefer to use soft water?—Yes.

5283. But that is soft water compared with the water which you use from your wells, which you say

J. Firth, Esq.
20 June 1867.

contains a certain quantity of iron, but I want to know whether apart from the presence of iron you know of any other objection to the use of water containing carbonate of lime?—I may say that we have used this water before the colliery was framed. We had the same water in its hard state unconnected with the iron, and we got it at a less depth. Our colliery is now 80 yards deep, and we then had the water at 20 yards, still it was hard water, and taking it at that point I should give the preference to soft water.

5284. Do you know through what strata it passed to the depth of 20 yards?—I do not know, but it was not iron. The water in our neighbourhood throughout has a slight proportion of iron in it.

5285. Are there any limestone beds in your neighbourhood?—No.

5286. You are probably well acquainted with the manufactures in France of a similar class to your own?—Yes.

5287. Do you know the results produced at Amiens in the dyeing of carpets, and Rheims in the dyeing of woollens?—Yes, they dye brighter colours than we do.

5288. Probably you are not aware that both the waters used at Amiens and Rheims come from a chalk country and contain a good deal of carbonate of lime?—No, I do not know the properties of the water that they use.

5289. That is why I wanted to elicit from you whether you knew positively from your own information that the objections which are raised to the use of hard water in your neighbourhood arose from the presence of carbonate of lime, which is the usual ingredient of hard water, or from some other substance, such as you have mentioned, namely, the presence of iron?—No doubt the water is very much injured by the presence of lime, and more so than it would be if the hardness had been produced merely by carbonate of lime; but at the same time, comparing soft with hard water, I should consider that even if our well water had no iron properties about it, soft water would be preferable for dyeing purposes.

5290. You stated just now that you consider that the colours produced both at Amiens and at Rheims are superior to the colours usually produced in this country?—Yes.

5291. And if I tell you that the waters used in both those towns are chalk waters, containing a good deal of carbonate of lime, and that they use no other waters, how do you reconcile that with the opinion which you before expressed that soft waters are better for dyeing purposes?—Because I say that we have no really good water for dyeing purposes in our neighbourhood excepting the town's water, and that is good water.

5292. Then all that you mean to say is that the town's water is better water than the water from your own well for dyeing purposes?—Yes.

5293. (*Chairman.*) So far as your evidence goes, I understand that it is entirely confined to the water which you have been using, either from the well or from the company who supply the town?—Yes.

5294. And that you are unable to state what are the properties of that water which you pump from the well, except that you have detected the presence of iron?—Yes, but since this question was put I have had our water analysed, and at foot give particulars of it; it was taken at an unfavourable time, the water being high in the old works.

5295. And that you believe in any case would be objectionable for dyeing and scouring purposes?—Yes, for certain colours it would.

5296. Do you know generally the watershed which supplies the water to the company?—Yes, I know the district.

5297. Is it moor or pasture land?—It is moor land.

5298. Is there any peat on it?—Yes, there is a great deal of peat there.

5299. Is the water coloured at all with the peaty matter?—No, it is very clear water.

5300. In times of flood have you observed any colour in the water?—I think that as a rule it runs in a very clear state into the reservoir which is very near the supply.

5301. Is it not of a brown peaty colour?—I think not.

5302. At least you have not observed it?—I have not observed it.

5303. (*Mr. Harrison.*) You get up near to the millstone grit where your source of supply comes from, do you not?—Yes.

5304. Is there any other point which occurs to you upon which you can give information to the Commission?—I can mention the revenue of the waterworks for 1864, and the different purposes for which it was used. For domestic purposes the revenue was 796*l.* 5*s.*, and for mill purposes 216*l.* It has very much increased since that time. In our district, particularly in Batley and Dewsbury, there is a large quantity of cloth of dark colours produced, and also blankets of dark colours, and for those purposes probably the advantage of soft water would not be so great as in our trade, because in a blanket it is not only necessary to have it clean and bright and white, which we always find soft water produces as compared with hard water, but also to have it soft.

5305. (*Chairman.*) Are you able to express an opinion as to the value of water in the manufacture of saxon wool?—We do not use saxon wool.

5306. But you are, no doubt, acquainted with the manufacture of Huddersfield and Leeds, and that district, where they manufacture fine cloth?—Yes.

5307. It would be very important for scouring purposes that they should have soft water there, would it not?—I should think so, for the trousering trade. They make there plain black cloths, and also fancy mixtures; and I should think, for fancy mixtures and trouserings which are dyed in the yarn, the soft water would be an advantage.

5308. (*Sir B. Phillips.*) Would not all light woollen fabrics be better dyed with soft water than with hard?—Yes.

5309. (*Mr. Prestwich.*) You are in the midst of a large coal district, are you not?—Yes, we are.

5310. Is the towns supply as soft as that from the Holmfirth reservoir?—Yes, it is as good as that. We find a decided advantage in dyeing with the town's water, and a decided advantage in scouring and cleansing with it.

5311. (*Chairman.*) I presume that the real cost of soft water compared with hard water is as nothing when compared with the increased value of the article in consequence of the bright clear colours which the soft water would produce?—Certainly, that is so.

5312. (*Mr. Prestwich.*) Do you know the relative quantity of water which you use for scouring purposes and for dyeing purposes?—I could not say that. We have such an abundant supply that we do not stint it at all. If we had it from the town and had to pay for it, no doubt we should regulate the quantity; but as we have the whole of the water to pump out of our works, we do not attempt to measure what quantity we are using.

5313. You state that you do use a certain quantity of water from the town; are we to understand that you use it for all your scouring purposes?—No, not for all; only for particular bright colours.

5314. I am not now speaking of dyeing, but merely of scouring?—For scouring in the same way. When we are scouring for light colours we should use soft water.

5315. You stated that your opinion was that an economy of 25 per cent. is produced by the use of soft water in the saving of soap. Can you tell us whether you are aware of any saving with regard to the use of dyes?—No, I cannot tell that, excepting in light colours; that is to say, I cannot tell the percentage, but I daresay I could ascertain it. There is one remark which I should wish to make with regard to the dyers in France. We find, as a rule, that the working dyers of England are not as good a class of men as the French working dyers; they are not so

well educated as chemists. The French dyers really are chemists, and they study the properties of the waters. They are scientific men; whereas the working dyers that we have in this country, as a rule, are ignorant men who merely work by practice, and do not analyse the thing. In fact, you are almost entirely in their hands in the dyeing process, because they will not even go to the extent of weighing the materials. They are not the class of men that they have in France; they are not educated, in fact, and they sadly want education.

5316. (*Sir B. Phillips.*) They know nothing of the chemical properties of the material?—Nothing at all.

5317. (*Mr. Prestwich.*) Can you explain how it is that two important towns in the north of France, which are becoming the great seats of woollen dyeing, would have become so unless the waters had been suitable for the purpose, the waters in both those cases being hard chalk waters?—I cannot explain it.

5318. (*Chairman.*) But there are other elements to be taken into account besides the question of dyeing, namely, the labour, the water, the materials, and the market also?—Yes. For some colours, no doubt, iron water is cheaper to dye with than others.

5319. (*Mr. Prestwich.*) It would appear from what you state, that the waters in your district contain little or no lime, and that the hardness arises from other sources?—Yes. I may remark that I have just come from Paris now, and I find that there is very great attention paid to the education of the working men by the Government; they are educated in all the various branches of manufacture—they are schooled for this sort of thing, so that, as a rule, the men in that branch are superior. Also, in England we have in the dyeing trades parties whose business is dyeing, and the masters at the head of those establishments are, no doubt, practical dyers themselves. Whereas, in our business, we send out more to dye than we dye ourselves. We only dye certain portions of our manufactures, and from that cause there is not that necessity for ourselves to become practical dyers. In fact, we have other portions of our business which are of more importance, and to which we give our attention.

The following is an analysis made of our water by by Mr. J. Chapman Wilson, F.C.S. of Leeds, viz.:—

"In appearance the water is at first slightly turbid, but "after standing a short time exposed to the air it deposits "an ochreous-looking sediment and becomes quite bright "and clear. When boiled it deposits a copious white sedi- "ment and incrustation. An imperial gallon contains "50·03 grains of solid matter, 0·14 grains of which is "organic and soluble matter. There are present the "following salts:—

"Carbonate of lime, "Sulphate of lime, } Chiefly.
"Carbonate of magnesia,
"Cloride of sodium,
"Carbonate of iron,
"Silicia.

"The total hardness of the water is 16°, the temporary "hardness or the hardness which may be removed by "bolling is 6°, and the permanent hardness which remains "after boiling is 9°. Carbonate of protoxide of iron is held "in solution in considerable quantity, indeed sufficient to "render the water objectionable for many manufacturing "purposes, such as dyeing, &c., and its hardness lessens "its value for washing and scouring. However, by con- "tinued exposure in an open reservoir the carbonate of "protoxide of iron would be thrown down as a sediment of "yellow peroxide, and the water thus be freed from the "soluble iron salt which is prejudicial."

Our own water dyes the following colours cheapest and best, viz.: black, blue, and magenta, but in all cases for washing off goods after being dyed, the towns' water is the best. And also in scouring or cleansing yarns or pieces the towns' water is the best, and effects a saving of 25 per cent. of soap used in scouring yarns; all other colours not specified are dyed cheaper and brighter with towns' water.

The witness withdrew.

SAMUEL JUBB, Esq., examined.

5320. (*Chairman.*) What business do you carry on?—I am a woollen manufacturer at Batley, near Leeds.

5321. What class of manufacture do you carry on?—Heavy woollens for winter wear, heavy coatings such as pilot cloth, Whitney's kerseys, Petershams, and those kind of cloth which contain some shoddy and a part mungo.

5322. (*Sir B. Phillips.*) Do you make those cloths for the London markets?—Yes.

5323. (*Chairman.*) Do you use the machine called a "devil" there for tearing up the old material?—Yes.

5324. Will you state to the Commission whether you manufacture from the wool, or whether you buy your yarns?—We purchase the wool and manufacture the goods out of the wool throughout, from the first process to the last; every process is done on our premises.

5325. What class of water are you using in the manufacture?—For our dyeing we are using the surface water which we collect in a dam, but for milling and scouring we are using the towns water almost entirely, I may say entirely.

5326. Why is that?—One reason is, that we have not got a supply of water adequate to our wants, and another is that the dam water would not serve both the milling and scouring process and the dyeing process, and we find that the towns water is much better for the milling and scouring process, and we can get a supply at present, and therefore we use soft water entirely for those purposes.

5327. What is the quality of the soft water?—It is similar water to that described by Mr. Firth, it is the same supply of water.

5328. Is your manufactory near to Mr. Firth's?—Within about a mile and a half.

5329. Then you take your water from the same company?—Yes, from the same company; it is not a private company, it is the waterworks established by the three townships of Dewsbury, Batley, and Heckmondwike.

5330. Are those waterworks under the municipal authorities?—Yes.

5331. But you yourselves have some catch basin, I think you said?—Yes.

5332. And you use that water for all ordinary purposes?—We use it for the dyeing process, but the towns water we devote entirely to milling and scouring.

5333. What is the nature of the water that you catch, is it not soft?—It is soft, but there is a little hardness in it, it is not as soft as the other water, it is rain-water of course.

5334. What does it pass through to make it hard?—I do not know why it should be hard.

5335. Have you had any analysis made of that water?—We had an analysis made two or three years ago, but it was with regard to a lawsuit that we were likely to have. I forget what the result of the analysis was, but a party was fouling the water with grease so that that analysis would not apply in this case.

5336. That analysis would detect the grease and not the lime, but was the investigation put in motion for the purpose of detecting the presence of grease, or was it with regard to the general qualities of the water?—It was put in motion for the purpose of detecting the presence of grease.

5337. Do you remember whether it was declared to be a hard water or a soft water?—No, but it could not have been declared a hard water, it has a certain

S. Jubb, Esq.

20 June 1867.

degree of hardness about it, but I cannot specify the amount.

5338. What is the character of the ground where this water is collected?—It is chiefly pasture land, the water runs off into a small rivulet or open drain.

5339. And that water is dammed up and settled?—Yes, it is collected in a dam and settled.

5340. (*Sir B. Phillips.*) Do you scour your own yarn when you buy them in the grease?—We do not scour the yarns, but we scour the cloth; we make up the yarns into cloth before scouring them.

5341. (*Chairman.*) What is your experience with regard to the use of what you call the towns water as compared with the water which you collect in the reservoir of which you have spoken?—We much prefer the towns water, it is far superior in all its effects, I mean both with regard to the saving of soap and with regard to producing brighter colour, and also it makes the cloth kinder, and at the same time I think firmer, so that it gives an advantage to the cloth as compared with the other water.

5342. Does it give it a mellower feel to the hand?—Yes, the cloth feels fuller in the hand, and at the same time it feels firmer.

5343. Is not it rather the result of the more perfect scour that you get rid of all the hardening effects of the manufacture by the use of soft water?—I think that may be so. I think the better you can get the grease out of the cloth, the cleaner it feels and the fuller it feels, and better in every respect.

5344. Have you instituted any inquiry for the purpose of ascertaining the relative saving by the use of the two waters?—I did put that question to our miller before I came away, and he told me that he thought that a saving of from 15 to 20 per cent. would be effected in the consumption of soap by the use of soft water as compared with hard water.

5345. (*Mr. Harrison.*) Is that in the mere cost of soap?—Yes, since we have used the towns water we have heard a great deal said about the great saving that was effected by the use of it, and therefore so I put the question to him. I do not know that we had ascertained it before.

5346. (*Chairman.*) What quantity of soap do you use in the course of a year?—About 800*l.* worth of soap.

5347. So far as your experience enables you to form an opinion, you would save about 120*l.* a year by the use of soft water as compared with hard water; that would be the absolute saving in the consumption of soap, but you would have the additional advantage of producing brighter and better colours, and cleansing your articles in order to give them a better handle, and thus enabling them to produce a better price when taken into the market?—Yes, it produces a superior cloth, there is no doubt about that.

5348. So that you could afford to pay a considerable sum for soft water for your manufacturing purposes?—We pay 6*d.* per 1,000 gallons for the towns water, and I should prefer to use it, I think, to having hard water at 3*d.* per 1,000 gallons or even 2*d.*

5349. Would you not prefer paying 1*s.* 6*d.* per 1,000 gallons for soft water for the purposes you have described, having regard to the saving that it effects?—We should not like to pay 1*s.* 6*d.* per 1,000 gallons.

5350. But supposing that it were a necessity and you could not obtain the water at a less price, would it not pay you as a manufacturer to give that price for it?—I do not know. I would not say even that it would not pay at that price.

5351. Supposing you could obtain hard water for nothing, would not it pay you to take soft water for manufacturing purposes even although you had to pay a considerable sum for that water?—That is a hypothetical question, and I should hardly like to answer it in the affirmative, but still I am not prepared to answer it in the negative.

5352. Have you any experience of the manufacture of the finer cloths at Huddersfield and Leeds?—I know in a general way the sort of cloths they produce.

5353. You do not use saxon wool, do you?—No, but we use Australian wool and colonial wool for the finer goods.

5354. Do you make flannels?—No.

5355. (*Sir B. Phillips.*) Have you any idea of what amount you pay for water?—Our last quarter's bill was 53*l.* for towns water.

5356. Is that the average; would you pay four times that in a year?—We are paying about 200*l.* a year now for water. We have not paid quite so much heretofore, but we have increased in the use of the towns water.

5357. How many hands do you employ?—From 400 to 500.

5358. (*Col. Harness.*) Could you say what proportion of that water is used for scouring?—It is nearly all used for scouring, we use very little for milling, the milling requires very little so to speak, the scouring the goods off is the process which requires a great quantity of water.

5359. (*Chairman.*) Is there any difference in the use of soft water as compared with hard for felting purposes?—Certainly; I think that the cloth is better felted by being scoured off with soft water. At least there is this property about the towns water, that I find the cloth is better felted after being scoured than it is when scoured by the other water. For a summer or two past we have run short of towns water, and we have had a good deal of goods to send out to other places to scour, where they have scoured them with hard water, and we have noticed that when the goods have been sent back they have been very much more slabby and loosely felted than our goods scoured with the towns water; they were not so firm to the hand.

5360. (*Mr. Prestwich.*) What distance are you from Leeds?—Eight miles south of Leeds.

5361. What is the nature of the supply to your reservoir?—It is from the country around; it is the watershed from off our local ground that flows into this dam.

5362. Is it a small stream that flows through your own grounds?—Not through our own grounds; it is a water right that we have.

5363. Is not the tract of country of a very similar nature to that from which the town supply is derived?—No, because all the water in the town supply falls on to moor land, on to the peat.

5364. Does the small stream from which you derive your other supply flow through a cultivated tract of country?—Yes, partly arable and partly pasture land.

5365. Does it pass through many villages?—No, it comes a very short distance. I should think it would not take its source more than a mile, if as much as a mile away.

5366. Is that water irony?—No; the water that we collect has a little hardness in it, but I do not know whether we should call it iron or not.

5367. You are probably not aware whether the hardnessis produced by iron, or by sulphate of lime, or carbonate of lime?—I am certain that there is no lime about it; it is not a lime district at all; it is a coal strata.

5368. The water simply falls upon the surface and runs off into a local stream, and you collect it at a certain point?—Yes.

5369. How can it, under such circumstances, be hard?—I do not see how it can have much hardness, but I was speaking to our dyer about it, and he said it was harder than the towns water.

5370. I suppose that some flowing water finds its way into that stream as well as the water that falls from the clouds?—Yes, there is a spring.

5371. (*Mr. Prestwich.*) Is there any source of impurity to that water?—Yes, there are sources of impurity, there is some sewage that flows into it.

5372. Is that found objectionable?—We do not like it, but we cannot help it.

5373. For your manufacturing purposes, would the presence of sewage injure the water?—Yes, I think it would be decidedly injurious.

5374. The water is not so clean as you wish it to be?—No.

5375. (*Chairman.*) Would the ammonia in that water have any effect upon your processes?—We use ammonia in dyeing.

5376. You use urine to a large extent, do you not, for cleansing purposes?—Yes, we do. We collect it in barrels; we send a man round with a barrel to collect it at different places.

5377. (*Mr. Prestwich.*) You have stated that your impression is that there is a saving of soap to the extent of 15 per cent.; is that impression derived from any direct experiments, or from a mere general opinion with regard to the matter?—I think that our miller has had so much experience in milling that his opinion would be about the mark. He has had several years' experience, and has been in the habit of using a great deal of soap, and I think that his estimate would be likely to be about correct.

5378. Can you give the Commission any opinion as to whether there is economy with regard to consumption of dyes in the use of soft water?—I understand that in some colours the use of soft water as compared with hard water does not effect any saving; for instance, in the case of blacks, but I think from what I can gather that upon the whole soft water is preferred for all colours.

5379. You have expressed an opinion that the use of soft water produces economy in the consumption of soap, and the object of my question was to ascertain whether there is also economy in the use of dyes?—Yes, I should say decidedly so, on the whole.

5380. (*Chairman.*) Independently of the production of a better colour?—Yes.

5381. Do you mean that the consumption of dyeing material would be lessened by the use of soft water?—That is my opinion without being able to state positively what the fact may be.

5382. You have been using the expressions soft and hard water, but you use them I presume relatively to the waters supplied by the town and the water which you collect from the stream?—Yes, we do not speak of them in a scientific sense or a chemical sense, but we speak of them as we find them adapted to our purposes.

5383. (*Sir B. Phillips.*) Do you know anything of silk dyeing?—No, I cannot say I know much of silk dyeing.

5384. (*Mr. Prestwich.*) Probably you heard the question which was put to the previous witness with regard to the circumstance that in the towns in France where they carry on dyeing of a similar class to that in which you and the other gentleman are engaged the water is chalk water of a hard quality?—I cannot understand how that should be. I should think that lime was antagonistic to our processes, either of milling or dyeing.

5385. But apparently you cannot support that opinion by any facts?—I know that we do not like lime, for lime is a very injurious thing in milling.

5386. I am speaking now merely with regard to colour not with regard to scouring. Are you acquainted with any facts as to the effect of lime upon colour?—I do not know that we have much experience with regard to lime water. I think our water is not impregnated much with lime but rather with iron; the water runs off the coal strata.

5387. (*Chairman.*) Would not the presence of lime give a very hard and harsh feeling to the fabric when made?—That is my impression. I think that lime is altogether antagonistic to softness in the cloth, or even to producing good colours; whether or not it may answer possibly for some colours I cannot say, as there is a great variety of colours. I know that formerly when we used our well water we could dye scarlets very well with it, but we could not wash them off, indeed the water turned them crimson. They could be dyed with the same water, but when they came to be washed off in the water they turned crimson. That arose from the presence of the iron in the water when it was used for scouring, but it would appear that in the dyeing the iron had been neutralized by some other agent.

5388. (*Mr. Prestwich.*) Is there any deposit of iron apparent in the streams or in the water channels?—No, I cannot say that there is in that channel which supplies our works.

5389. (*Chairman.*) Locally have you observed in the running streams any oxide of iron?—No, there is no ochrey water about us.

5390. (*Mr. Prestwich.*) Is there no analysis of this water that you can lay before the Commission?—No, I have not an analysis of our local waters at all, but iron is the principal ingredient I think that characterises the local waters; that is to say, the well waters which are pumped out from the ground.

5391. (*Chairman.*) Have you ever had any analysis made except for the purpose of the action to which you referred?—No, I believe not.

5392. (*Mr. Harrison.*) How far are you from the Low Moor ironworks?—About seven or eight miles.

5393. Do all those ironstone beds in that district extend through the hills to Batley?—I should think not.

5394. They are actually working the coal at Batley, and they have been getting the coal there for many years, have they not?—Yes.

5395. I believe that until they made the railway there the coal was not so extensively worked as it has been lately?—No, perhaps not, although I do not think there is much difference. There is a colliery opened at Morley which, no doubt, was principally opened on account of the railway, which is immediately adjoining us, but that is not in the township of Batley, it is in the township of Morley. We have coal about us in great quantities.

The witness withdrew.

JAMES ALFRED WANKLYN, Esq., examined.

J. A. Wanklyn Esq.

5396. (*Chairman.*) What position do you hold?—I am Professor of Chemistry at the London Institution, Finsbury.

5397. How long have you been professor there?—Four years.

5398. Has your attention been directed to the qualities of water?—It has.

5399. And to the qualities of the several waters supplied to the metropolis?—It has.

5400. Have you made any analysis of the water, or of all the waters?—I have examined several of the waters of the metropolis, but I have mostly examined artificial waters made by myself. Those were examined first, and then afterwards the waters supplying London were examined.

5401. Will you state to the Commission first, what was the result of your examination of the several waters supplied to the metropolis?—The result has been, that the New River water, as far as organic matter is concerned, is very fair, but the other waters are bad.

5402. Will you go on to describe the result of your examination of the water?—The Southwark and Vauxhall water is very bad indeed, it contains seven milligrams of white of egg in a litre; that is to say, the nitrogenous matter in an albuminous form (and in my report I mean to return the nitrogenous matter as albuminous matter or white of egg, and as urea). Those two kinds of nitrogenous matter are typical kinds, and they are good representatives of the different kinds of nitrogenous matter. The white of egg is the nitrogenous matter that forms the tissues, and is the undecomposed nitrogenous matter, and the urea is the tissues decomposed.

5403. Does the Southwark water contain a large proportion of this substance?—Yes, it contains a large

J. A. Wanklyn, Esq.

20 June 1867.

proportion of organic matter undecomposed, and it contains a small proportion only of organic matter decomposed to urea.

5404. Have you examined any other waters?—Yes, the New River water, and the water of the East London.

5405. What is the condition of the water of the East London?—The value is 3·2, the Southwark and Vauxhall value is 7·3, and the New River 3·0.

5406. There are two waters supplied to the East London district, which was your sample taken from?—It was taken from one of the street mains.

5407. Do you know the source of supply to that main?—I do not know the source of supply.

5408. How is that water, as compared with the New River and the Thames water at Thames Ditton?—It is very much better than the Thames water, and worse than the New River water.

5409. Then the New River water is superior to the Thames?—Yes, the New River water is superior to the Thames.

5410. Where did you take your sample of the Thames water from?—I had a great many samples of the Thames water. I cannot tell the exact point where they were taken, but a great number of samples of the Thames water have been taken.

5411. You did not take it I presume at London Bridge?—Water was taken from London Bridge, but samples were taken higher up.

5412. Did you take any of your samples above the tidal influence?—Yes, some samples were taken above the tidal influence, and other samples were taken below the tidal influence.

5413. You have drawn a contrast between the New River water and the Thames water. I want to know whether the waters which you so contrast were samples taken above or below Teddington lock?—I contrasted with samples both above and below Teddington lock.

5414. You are comparing a sample of Thames water with the New River water, where was the sample taken from?—The sample which I have compared with the New River water was a sample taken above Teddington lock.

5415. Was it taken at the point where the water companies take their supply. It is important that the Commission should know where the water was taken from, because even if taken above Teddington lock it might have been taken at a point where the sewage of Kingston might affect it very seriously?—I cannot give you the exact point.

5416. (*Mr. Harrison.*) Have you analysis of any of the London waters taken from any of the supply pipes in the streets?—Yes; in the case of the East London water the water was taken direct from the main. I have not the particulars here, but I can supply the Commission with the exact particulars.

5417. (*Chairman.*) Could you put in a table showing the result of your examination of the several waters, where the samples were taken from, and the date?—Yes, I will do so; the samples have all been taken recently, or within the last three or four days. That, I think, will be sufficient with regard to the date.

5418. Is there any other point to which you desire to call the attention of the Commission?—I should desire to say that my attention has been chiefly directed to perfecting a method of analysis, and the method has only just been made sufficiently perfect to be worked. I have been operating upon artificial waters with the view of testing the method, and I have not had time or opportunity for giving the method a fair chance at present. There is one point to which I should like to direct attention. There is a passage in a report, dated 1856, on the metropolitan water supply, by Professor Hofmann and Mr. Blyth, which explains very well what has recently been done. "Very little is known "of the nature of the ill-defined substances which "constitute the organic matter generally found in "water. Berzelius distinguishes two substances, "crenic and apocrenic acids, which slightly differ in "their chemical deportment, but these two bodies are "as yet scarcely chemically examined, and much "doubt still hangs over their individuality and even "over their existence. The organic matter in water "has been divided into nitrogenous and non-nitrogenous matter, but all we know is that certain "varieties of the organic matter found in water contain nitrogen, which is readily shown by treating "them with hydrate of potash, when abundance of "ammonia is evolved. The opinions of chemists are "divided as to the manner in which organic matter "in water is capable under certain conditions of producing a deleterious effect upon the animal economy. "But it is now generally admitted that the substances "which constitute the organic matter of water act "injuriously, by no means in consequence of being "poisonous themselves, but by undergoing those great "processes of transformation called decay and putrefaction, to which all vegetable and animal matter "is subject when no longer under the control of "vitality, either in plants or animals. These putrefactive processes either give rise to the formation "of poisonous bodies or they act simply as ferments, "generating similar processes of decomposition in the "substances composing the animal organism. Now, "with special reference to the last mode of action, "it is well established by general experience that "nitrogenous substances are infinitely more liable "to undergo putrefaction than organic bodies from "which nitrogen is absent," showing that Professor Hofmann thought, and it is generally admitted that the nitrogenous organic matters alone are those which we have any need to pay attention to. "And hence "the very general and correct opinion that the "deleterious character of organic matter in water is "proportionate to the amount of nitrogen which it "contains. Could this nitrogen be estimated with "any degree of accuracy, such an estimate would "certainly afford the most satisfactory element in the "examination of the organic matter. Unfortunately "this estimate is attended with very considerable "difficulties. The nitrogen of the organic matter "which has undergone putrefaction and has therefore ceased to be deleterious remains in the water, "partly as ammonia, partly as nitric acid. It would "therefore by no means be sufficient to evaporate the "water and to determine the amount of nitrogen in "the residue. It would be absolutely necessary to "estimate also the nitrogen present in the form of "nitric acid and of ammonia, and only after the "deduction of their joint amount from the total "amount numbers would be obtained which, representing the quantity of still putrescible nitrogenous "substances, would afford within certain limits the "necessary data for a comparison of the organic "matter present in different waters. It is obvious "that this mode of proceeding is very complicated, "and not likely to furnish trustworthy results unless "carried out with the greatest circumspection, and "with all the appliances which the modern progress "of analytical chemistry can suggest." I have to remark that the method of determining the organic matters which I use is a very simple one,* and can be carried out in about three hours, and the determination is a perfectly direct one. I do not determine the total nitrogen in a water and then determine the nitrogen present as ammonia and nitric acid and give you the difference, but I determine directly the nitrogen present as organic matter, and that you will see is an important thing. The project of 10 years ago, (and it has been tried to be carried out, and it is admitted that it will be very difficult to carry it out,) was to give you the organic matter by a double process, giving you a difference; but my method is a

* The method of determining organic nitrogenous matter here referred to is the joint discovery of Messrs. E. T. Chapman, Miles H. Smith, and myself.—*Vide* "Laboratory," weekly journal.

All the experiments referred to were made in the laboratory of the London Institution, in many cases by Messrs. Chapman and Smith.—J. A. W.

direct one. I give you directly the nitrogen which is present in the organic matter. And there is another point which should also be mentioned. It is necessary to examine water fresh, and not after it has been kept a day. I had an example in which I examined a London water immediately it was taken, and then examined it 18 hours afterwards and I found a very perceptible difference.

5419. (*Mr. Harrison.*) Were the samples hermetically sealed in both cases?—The water was taken in a Winchester quart bottle and immediately examined, and a portion of the water in the Winchester quart bottle was kept till the next day and was examined again, and there was a very sensible difference. It was not sealed, but simply stoppered.

5420. I presume you have been on a matter of such vast importance in communication with Dr. Frankland?—I spoke almost daily to Dr. Frankland about it for some time.

5421. You are aware, are you not, of the monthly reports which Dr. Frankland makes, and the analyses which he gives of the London waters?—Yes, I know them very well.

5422. Is the conclusion which you have arrived at that those results are not sufficiently satisfactory?—I believe that they have no value whatsoever as regards the organic nitrogenous matters.

5423. Having been in consultation with Dr. Frankland, can you tell us what he thinks of your process?—He has admitted to me the extreme value of the process.

5424. He has not yet adopted it, has he, in his analyses?—He has made experiments upon it. I am not aware that he has as yet adopted it, but he has admitted to me that it is the process. I may mention that Professor Way has adopted my process, and is working it.

5425. (*Mr. Prestwich.*) Has not Dr. Frankland, in the results which he has given for the last two or three months, introduced a new method of analysis?—His method is literally carrying out what Professor Hofmann sketched out in his report. He gave you the organic matters by this method.

5426. He determined the total quantity of nitrogen, and then apportioned a certain quantity of it to nitrates and nitrites and a certain quantity to ammonia, and he took the difference, I think, as the organic matter?—Yes. He gives you the total nitrogen in water present as nitric acid and ammonia, and determines the organic nitrogen, but Dr. Frankland himself admits that the method is unsatisfactory to the last degree.

5427. Still Dr. Frankland thinks it is the best mode within his knowledge of obtaining the desired result?—It was the best mode and the only mode known at the time.

5428. I presume that he considers it the best mode now known, inasmuch as he still continues to give the results obtained by such a method. In what way does your process differ? I mean, what is your mode of conducting the analysis for organic matters?—The mode is this: I take the water and boil it with carbonate of soda, and I take a litre of water, and I first collect a third of the distillate. In that distillate there will be all the nitrogen that was present as ammonia and as urea. I then add caustic potash and permanganate of potash and distil, and the second distillate contains all or very nearly all the nitrogen that was present as albumen. I may mention that under the term albumen I mean albumenoid matters. I have made this experiment. I have taken a certain quantity of white of egg, and weighed it and put it into a water and obtained very nearly all the nitrogen that it contained in the form of ammonia, and that is the most direct evidence that could be had.

5429. To what extent does the application of your process and that of Dr. Frankland's differ in their results; that is to say, supposing you take an analysis of the London waters as given by Dr. Frankland in any given month, he shows that there is a certain amount of nitrogen present in the ammonia, a certain quantity of nitrates and nitrites, and a certain quantity derived from—I think he terms it—sewage matter. What is the difference in the results obtained by the application of your method?—We get the nitrogen that is present as urea and as albumen, and Dr. Frankland's method really does not give that at all. In evaporating the water down to dryness, in order to get the residue, the urea is lost; it is converted into ammonia in great part, so that Dr. Frankland's first value for total nitrogen is defective. If Dr. Frankland's method were good it would be necessary that his determination of total nitrogen should be good, and that his determination of nitrates and ammonia should be good. The total nitrogen is taken from the nitrogen in the residue; now before you can get the residue the greater part of the urea is lost. I tried an experiment in which I took a litre of water and put into it a gramme of urea and evaporated it down. I did not get more than a decigramme of urea left.

5430. Do the results of your analyses give a larger quantity of free organic matter present in water?—Yes, a larger quantity;* and Dr. Frankland's organic nitrogen is totally irregular, for the method is not even regular.

5431. Can you tell us what the extent of difference is between you and the returns published every month by Dr. Frankland?—I will put in tabular forms of the analyses. The method is quite new, and that will account for the fact that I have really no adequate set of analyses of the London waters.

The witness delivered in the following tabular statement:

TABLE I.†

SOME WATERS used for the ORDINARY SUPPLY of LONDON.

Date when taken.	——	Parts in 1,000,000. I. Ammonia originally present, and from Urea.	II. Ammonia from Albumenoid Matter.	III. Moist White of Egg.
19 June	New River, from cabstand near Moorgate Street railway station.	Not taken.	0·090	3·213
21 June	Water from same place.	0·015	0·084	2·999
18 June	East London, water from cabstand in Whitechapel.	0·030	0·089	3·177
19 June	Southwark and Vauxhall, cabstand near London Bridge.	Not taken.	0·206	7·359
21 June	Same, taken from same place.	0·039	0·204	7·283

TABLE II.

WATERS from PUMPS in or near the City of LONDON.

Date when taken.	——	Parts in 1,000,000. I. Ammonia original, and as Urea.	II. Ammonia from Albumenoid Matter.	III. Moist White of Egg.
28 June	Pump in Bishopsgate Street opposite Houndsditch.	7·500	0·255	9·004
27 June	Pump in Bartholomew Lane (east end of the Bank of England).	5·500	0·240	8·568
21 June	Pump in Great St. Helen's.	3·750	0·180	6·426
28 June	Pump in St. Paul's Churchyard, north side.	0·060	0·135	4·819

* The analyses referred to are the March analyses.—J. A. W.

† The analyses given in these four tables were made in the laboratory of the London Institution by E. T. Chapman, M. H. Smith, and myself.

TABLE III.

WATERS from VARIOUS SOURCES.

Date when taken.	——	Parts in 1,000,000. I. Ammonia original, and as Urea.	II. Ammonia from Albumenoid Matter.	III. Moist White of Egg.

TABLE IV.

WATERS free from ORGANIC MATTER containing NITROGEN.

Date when taken.	——	Parts in 1,000,000. I. Ammonia originally present.	II. Ammonia as Albumenoids.	III. Moist White of Egg.
	Distilled water, distilled in the laboratory of the London Institution.	0·060	0·000	0·000
June 24	Water from Cold Harbour, Dorking, (from the green sand).	0·015	0·000	0·000
„ 25*	Caterham water, from waterworks, after Clarke's process.	0·040	0·000	0·000

* Examined June 26th..

NOTE ON THE TABLES.

Column I. contains the ammonia originally present in the water, and also the ammonia derived from the decomposition of urea.

Column II. contains the ammonia derived from the decomposition of albuminoid matter.

Column III. contains the amount of albumenoid matter expressed as white of egg (moist), and is calculated from Column II. This column is inserted in order to give some idea of the amount of organic tissue to which the albumenoid ammonia would correspond. The data for this calculation have been furnished by an analysis of white of egg undried and fresh. 2·80 parts of ammonia correspond to 100 parts of white of egg.

REMARKS ON THE TABLES.

Table I. If Dr. Frankland's published tables of London waters be examined, it will be seen that four out of the eight London waters were free from "organic nitrogen" in February, that in March all the London waters were free from "organic nitrogen," and that in May all were rich in "organic nitrogen," the New River being the worst. This calculation is made according to Hofmann and Blyth's rule, by subtracting from total nitrogen the sum of the nitrogen present as nitric acid, nitrous acid, and ammonia. It will be observed that there is a total want of agreement between these results given by Dr. Frankland and those which I have the honour of presenting.

According to Dr. Frankland's May table, "New River contains ·076 parts of" organic nitrogen in 100,000 parts of water. This is equal to rather more than 0·760 parts of albumenoid *ammonia* in 1,000,000 parts of water. We obtain 0·090 and 0·084 parts of albumenoid *ammonia* in 1,000,000 parts of New River water taken in June.

Table II. I have to call attention to the horrible state of the first three pumps.

Table III. I have to notice that Thames water taken from the river at London Bridge is better in regard to "organic nitrogen" than Dr. Frankland's May table represents New River water to have been. The third Thames water which had been kept for some days illustrates the alteration which a very bad water may undergo on keeping.

I beg to call attention to the fact that "Loch Katrine" water is inferior, organically considered, to New River water.

Table IV. shows that there are spring waters which are absolutely faultless in regard to organic nitrogen. I have to add that in my opinion it will not be difficult to find many such spring waters, and that the water of lakes and rivers is not the best that can be found for the purpose of supplying towns with drinking water.

5432. (*Chairman.*) Have you had any discussion with Dr. Miller upon this point?—I have spoken with him and he thinks my method promises well.

5433. But he has not adopted your system, has he?—The system is only a few weeks old, and I cannot tell whether he has or not, but Professor Way is adopting the system.

5434. Professor Way is now examining the London waters, is he not?—Yes, I think so.

5435. And is he adopting the system which you propose in the examination of those waters?—Yes.

5436. (*Mr. Harrison.*) It is only, as I understand, within the last week or two that you have arrived at a positive result in those experiments?—The method is about a month old; that is to say, about a month ago I was certain that the method was workable, but it is only within the last week or two that little difficulties of detail have been got over; in fact, it is only just now that the method is in that perfection that it can be used.

5437. (*Chairman.*) What is the saving in time in making an analysis of water by your system as compared with the old system?—I can make a determination of the organic matter in water in a couple of hours with ease, and I cannot make a determination by Dr. Frankland's method under two days. I have myself made determinations by Dr. Frankland's method; in fact under his own eye almost.

5438. Have you made an examination of the same water and compared the results?—In one instance I did.

5439. What was the result of that comparison?—Part of the result of the comparison was this, that some of the nitrogen which he returned as ammonia originally present I return as urea, and also that I get a certain value for the albumenoid nitrogen, whereas Dr. Frankland gets no certain value for it. But the difference in the ammonia obtained as such is probably due to this cause, that the water which I operated upon was examined immediately I got it home, or within an hour or two of its being taken, and Dr. Frankland's would be kept a day or two first.

5440. (*Mr. Prestwich.*) During which time a change goes on in the water, which produces ammonia?—The urea becomes ammonia, and carbonic acid and the albumenoid nitrogen is changed also.

5441. (*Chairman.*) Has your attention been directed to the question of constant supply of water as compared with the intermittent system now in operation?—I have not paid any attention to that subject.

5442. Do you think that for purposes of health water taken immediately from a pipe would be preferable for drinking to water taken from tanks, or vessels of any kind in which it might have been stored in a house?—There is no question that small cisterns in houses are very bad indeed. I can mention a fact upon that subject which is of importance. The New River water was taken directly from the main and examined, and there was only a trace of albumenoid matter in it, but some New River water

was kept in a cistern in my own laboratory, which is rather a damp laboratory, was examined, and there was found in it a sensible quantity of albumenoid matter. I am sure that keeping water in cisterns tends to generate this albumenoid matter; I should mention, however, that this cistern has not been cleared for years.

5443. (*Mr. Prestwich.*) Have you tested for the presence of organic matter in any of the spring waters round London?—Not in any of the spring waters round London, but I have made examinations of water from some of the springs in London itself; from the pump in Berkeley Square, for instance, and from a pump somewhere in the East of London, which was a wretched water indeed.

5444. But have you examined the water of springs from any part of the chalk, for example the springs at Grays, or the springs in the valley of the Lea?—I have not examined them.*

5445. Have you examined the water of the artesian wells in London?—Not yet.

5446. (*Mr. Harrison.*) You have made an analysis of the Southwark and Vauxhall water, have you not, and you say that the quality of that water is bad?—It is very bad.

5447. Was that water taken from their mains?—Yes, it was Thames water taken direct from the main.

5448–49. How does that analysis agree with Dr. Frankland's, who has reported in the last monthly report that he considers all those waters perfectly innocuous?—In the one that I refer to,† Dr. Frankland returns rather a higher value of ammonia present as ammonia, and I return a lower value of ammonia. Then I return a quantity of nitrogen present as albumenoid matter, and I believe Dr. Frankland returns no organic nitrogen at all. I have not Dr. Frankland's analysis to refer to at the moment, but as far as my memory serves me, Dr. Frankland returns no organic nitrogen in the water, and I return two decimillegrammes of ammonia per litre, or calculated into white of egg, 7·3 millegrammes of white of egg; that is to say, of albumen, reckoning it in a wet state just as you get it out of the egg. I made analyses of the white of egg as it is in the egg, without any drying or anything of the kind, in order to determine the nitrogen directly by the ordinary method, so as to have a term in which to express this organic matter.

5450. (*Mr. Prestwich.*) You merely use it as a term of comparison?—Merely as a term of comparison.

5451. (*Mr. Harrison.*) What is the result which you have arrived at as to the wholesomeness of that Southwark and Vauxhall water?—It must be very dangerous. I have no doubt whatever that it is dangerous, for this albumenoid matter may be organic germs of all kinds, and, in fact, the very worst things that there could be in a water. There is a point which ought to be mentioned. What are supposed to be the worst things that can be present in a water are germs that may set up a kind of vegetation within us, and if there are any of those germs in a water the albumen in the germs will be converted into ammonia by this process of analysis of mine, so that there is an actual measure of the possible amount of germ.

5452. (*Mr. Prestwich.*) How can you distinguish between that which is converted into ammonia and the ammonia originally present in water?—If there is ammonia originally present it distils over with the first third of the water, if you put carbonate of soda into it. Those germs are pretty stable, and they are only broken up completely by potash and permanganate of potash. I made an experiment with distilled water, and distilled with potash and permanganate of potash, and got no trace of ammonia after removing the trace of ammonia originally present. I have taken a water into which albumen had been put, and put in some carbonate of soda, and distilled and got off traces of ammonia. I put in potash and got off traces of ammonia, and I then added permanganate of potash and got a quantity of ammonia. I have taken distilled water and put into it a weighed quantity of white of egg, and got out all the nitrogen in the form of the ammonia.

5453. Are you sure that you can separate the ammonia originally present in water from the nitrogenous matter?—Yes, I have no doubt whatever on that point. I am quite certain of it. I made an experiment in which I put a hundred times as much ammonia into a water as can be present in a natural water, and distilled over, testing the first distillate, and by the time the water had been half distilled over there was no ammonia. The test which I use for ammonia is Nessler's test; it is a test of extraordinary delicacy, and I never test for albumen until I have first distilled off at least one-third of the water with carbonate of soda, and until the distillate gives no reaction with Nessler's test. I have never given the value for albumen unless I have first completely cleared the water of any ammonia by boiling it with carbonate of soda, and a water which will allow you to distil it from carbonate of soda without giving that which will affect Nessler's test is free from ammonia.

5454. Those analyses of organic matter are analyses of very great delicacy and difficulty, are they not, and there is great difference of opinion among chemists with regard to the best mode to be adopted?—There has been great difference, but I do not apprehend that there will be any longer any difference when our method is fully known.

5455. But that method is not yet fully known?—It is not fully known, this evening I am about to read a paper on it at the Chemical Society, and this paper will be the first complete publication of the method.

5456. (*Mr. Harrison.*) Have you applied your method to any of the pure waters?—I have applied it to distilled water, which is the only pure water.*

5457. I mean to any soft water?—No, not to any soft water. I have applied it to distilled water, because for the method to be worth anything it must give no reaction with distilled water, and my method has given nothing with distilled water; it has given a slight indication of albumenoid matter even with the New River water.

5458. Do you consider the New River water from that analysis to be a perfectly good and wholesome water?—I could not say so; it certainly contains a trace of albumenoid matter, but it is the water that contains the least of the London waters.

5459. But do you know of any water that has been submitted to your process which would contain no trace of it?—I have not examined any water from the country so that my opinion really is not of very much value upon that point. Distilled waters give no trace of albumenoid matter, but I have never examined by my method any of the waters which are reported as being extremely good waters.†

5460. (*Mr. Prestwich.*) Then you do not agree with Dr. Frankland that by the time the Thames water or the New River water is delivered in London, after having passed through the filtering processes, are so far oxydised as to have all the organic matter converted into nitrates and nitrites of ammonia?—I am sure that that cannot be so, for I have obtained this reaction for albumenoid matter in those London waters, and the test is this. The water is mixed with carbonate of soda and a distillate taken, and when the distillate shows no sign of ammonia by Nessler's test, then potash and permanganate of potash are added, and the appearance of ammonia is a sign of albumenoid matter.

5461. (*Mr. Harrison.*) How long is it since you communicated with Dr. Frankland upon your method?—Within the last week.

* Since giving this evidence different waters have been examined.—*Vide* Report sent in.—J. A. W.

† The March table of analyses was referred to.—J. A. W.

* *Vide* Report.—J. A. W.

† Since giving this evidence I have found some waters quite satisfactory.—J. A. W.

J. A. Wanklyn, Esq.

20 June 1867.

5462. Has he been present when you have gone through the whole process?—He has never seen the process worked in my laboratory, I have never made any experiment before him.

5463. In the case of Professor Way, have you gone through the whole process with him, or merely described it to him?—Not to him, but I know that his assistant is practising the method.

5464. You are not able to say whether you have as yet found any waters that are perfectly free from organic matter?—I have found distilled water free from albumenoid matter, but I have really never examined any of the reputed good waters, and therefore I cannot say whether they contain albumenoid matter or not.*

5465. (*Mr. Prestwich.*) Might not this albumenoid matter be derived from either vegetable or animal substances?—Yes, precisely.

5466. Therefore it would not necessarily be an indication of sewage contamination?—No. The indication of sewage contamination is the urea reaction. Urea gives up all its nitrogen in the form of ammonia by distilling with carbonate of soda alone, but albumen does not give up any of its nitrogen with carbonate of soda alone, but only with potash and permanganate of potash; so that I can distinguish between urea and albumen. If you put into one water a little urea, into another a little urea and albumen, and into a third albumen only, I could return the one as urea, the other as a mixture, and the third as albumen.

5467. Can you determine separately the quantity of ammonia, the quantity of urea, the quantity of albuminous matter, and the quantity of nitrates and nitrites?—The quantity of nitrates and nitrites does not enter into my method; that is to say, I do not give you the value in nitrogen, but always in ammonia, and my reagents do not convert nitrates and nitrites into ammonia.

5468. How do you account for the nitrogen present in the nitrates and nitrites?—I account for it in this way—it comes partly from atmospheric nitrogen which has been oxidised, and partly, I believe, from the chalk itself; for there is no doubt that chalk contains nitrogen, and also from sewage if that be present.

5469. Does not the presence of nitrogen in the nitrates and nitrites interfere with your method in any way?—Not in the least. I give a direct experiment in which I put nitrate of potash and nitrite, and there is no interference.

5470. You say that there is a certain quantity of albuminous matter present in the New River water; do you find that there is any free urea?—It is questionable. The quantity is very minute, indeed so minute that it is questionable whether there is any; but of albumenoid matter there is certainly a little.

5471. And in other London waters have you detected any?—In some of them there is what may be a larger quantity of albumenoid matter, and in others less.

5472. Do you find urea in them?—I find urea in small quantities only, and so small as to render it uncertain. When the quantity falls below a certain mark you cannot be absolutely sure whether there is any at all. The quantity of urea in the London water is, as a rule, very minute, so minute that it is hardly possible to say whether there is any or not.

5473. Has not albuminous matter been, I believe, found even in the deepest spring water where you would not suspect the presence of any organic matter?—Possibly that may be so, but I have made an examination of water from a London well and the water is wretched to the last degree, in the sense that it contains nitrates and nitrites of ammonia present as such, but it does not contain more than traces of albumen or traces of urea.

5474. Do you know what well it was from which that water came?—It is a well somewhere in the east of London.

5475. Is it an artesian well or a surface well?—A surface well, and the supply is really from a graveyard. It was taken as an example of very bad water indeed, but strange to say it was not found to be so bad as might have been expected. The total amount of nitrogen in it was enormous, but it was chiefly present as nitric acid and ammonia, and there were only traces of the other matters.

5476. (*Mr. Harrison.*) What do you assume to be the source of such albumen as you find in those waters?—A part of it would be sewage. I should say that the source is sewage in the case of the London waters.

5477. (*Mr. Prestwich.*) But you stated just now, did you not, that you could not distinguish whether the albumen might have been derived from animal matter or from vegetable matter?—Yes, it cannot be said at all with certainty.

5478. Therefore it would not be a necessary conclusion that it would be from sewage?—No, not at all.

5479. (*Chairman.*) Then you do not entertain the opinion that the sewage discharged into a river at point A, and carried down the stream for two or three miles, would be so broken up as to lose its deleterious properties?—No, I am sure it would not. All the urea that is in it is for the most part decomposed, but the albumenoid matters are not decomposed, and those you will get.

5480. Then all waters used for domestic purposes you assume should be intercepted?—Certainly.

5481. And that no length of time or volume of water would destroy the evidence of pollution which you have described?—Nothing that is practicable.

5482. It has been stated in evidence before us that if you pour into water a volume of sewage equal to five per cent. of the volume of water into which it is cast, the water will so operate upon it in deodorising and destroying and breaking up its elements into its primitive elements in fact, that it would no longer be sewage or possess any of its noxious qualities. You apparently hold a contrary opinion?—This I am sure of; the urea in the sewage in such a water would be very readily broken up into ammonia and carbonic acid, and a little exposure would dispose of the urea, but the albumenoid matter in sewage is extremely persistent, and one of the results of the whole investigation is this, that albumenoid matter is very persistent indeed, and you could not depend upon any treatment such as you have mentioned getting rid of the albumenoid matter.

5483. It was stated further in evidence that of the sewage discharged at Windsor, for example, no traces can be found three miles below Windsor?—I am sure that is incorrect. I am sure I could find out albumenoid matter in it.

5484. (*Mr. Prestwich.*) Supposing you extend the length of flow from three miles to 20 miles, what would be the result?—I have not made a direct experiment upon that point, but in my opinion you would get rid of all the urea, but you would still have the albumenoid matters.

5485. But will not certain changes take place, even in the albumenoid matters?—Yes, certainly; but the change is very slow, and it is very irregular. The change in urea is very rapid, so that you have to operate upon water recently taken in order to get your full quantity of urea.

5486. How do you account for the fact which you just now mentioned, that in the well in the east of London, into which the drainage from a churchyard passed, the albuminous matter and the urea had been so much got rid of that there were hardly traces of them remaining?—I imagine that what would leave the graveyard would be chiefly urea, and not albumenoid matter; but of course it is an ancient graveyard.

5487. Still, in the case of all the water from the shallow well springs in the east of London, the gravel is so permeable that it is charged with organic matter of all sorts?—In the case that I mentioned one would

* *See* Report.

think that all the albumenoid matter which would easily pass into solution would have passed away long ago, and now one is getting the urea, and in fact the products of the decomposition of masses of albuminous matter.

5488. Have you paid attention, in a sanitary point of view, or with regard to its application to manufactures, to the relative advantages of the use of soft and hard water?—Very little, but I have paid a little attention to it. I have no doubt that soft water is preferable to hard.

5489. You have mentioned that in a cistern exposed in your laboratory a larger quantity of nitrogenous matter was found to be present than in the water taken from the main?—Yes, of albumenoid matter, and I imagine that the source of it was vegetation actually in the cistern.

5490. Are you of opinion that water so exposed in cisterns in private houses, or in courts, or elsewhere, whether soft or hard water, would become rapidly contaminated by the presence in the air of any offensive matters?—I have no data to form an opinion upon that point.

5491. When you say that you think soft water would be preferable water to use, upon what do you ground your opinion?—It will wash more perfectly than hard water will. Practically you cannot wash yourself with hard water.

5492. But what is your opinion with reference to its qualities as a drinking water?—I think there are no data to show that it is preferable as a drinking water to hard water.

5493. With regard to washing water, we have had evidence of the economy of soft water, and with regard to its use in manufactures, I think you were present when the two previous witnesses gave their evidence with respect to the use of water in dyeing and scouring; do you agree in opinion with those witnesses?—I have had some experience in manufacturing chemistry, and I can answer with certainty that soft water is far preferable to hard for dyeing.

J. A. Wanklyn, Esq.

20 June 1867.

5494. May I ask you upon what your opinion is founded?—You get much more regular results, and the colour is more soluble.

5495. Have you ever made any experiment or investigated the subject in any towns where dyeing is carried on?—I have not made experiments directly to determine that point, but in dyeing it is of great importance that the colour should remain in solution as perfectly as may be, and any precipitation of carbonate of lime carries down some of the colours, and the bath becomes irregular directly. I know as a fact, that in making specimens for dyers, it is desirable to use distilled water.

5496. But you have no direct knowledge yourself with regard to the use of it, either by experiment or by the experience of manufacturers?—I have only a general experience with regard to it. Perhaps I may be permitted to observe, with respect to my difference of opinion from Dr. Frankland on the subject of the analysis of water, that there have been several discussions between us at different times. There was a question between us about the validity of a test, and he now admits that the test is invalid.

5497. (*Mr. Prestwich.*) Was that the permanganate of potash test?—It was a test for nitrates. Dr. Frankland's method depends upon the double determination of nitrogen, the determination of the total nitrogen, and the determination of nitrogen as nitrates and nitrites. It has been shown that the Pugh test totally fails, and Dr. Frankland now admits that it totally fails.

The witness withdrew.

Adjourned to Thursday next at 11 o'clock.

Thursday, 27th June 1867.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS.	JOSEPH PRESTWICH, Esq.

JOHN ROBINSON MCCLEAN, Esq., examined.

J. R. McClean, Esq.

27 June 1867.

5498. (*Chairman.*) You are a civil engineer, as we all know, and past President of the Institute of Civil Engineers?—Yes.

5499. You have I believe directed your attention to the question of an improved water supply to the metropolis?—I have for upwards of 20 years.

5500. In 1849 you had some plan, had you not, for the supply of London?—Yes, a company at that time deposited plans during two sessions for the improvement of the supply of water to the metropolis. (*The witness delivered in a plan and section; see Appendices T (1) and T (2).*

5501. Were you before Parliament with that plan?—We were twice, but it was thrown out on second reading the first time and stopped on Standing Orders the second time. It was never examined before any committee.

5502. Was the opposition promoted by the existing companies, or how do you account for the rejection of the scheme?—At that time there was a great clamour for an improved supply of water, and a number principally of professional men formed themselves into a company for the purpose of improving the supply, but the result was that the existing companies improved their supply, and our scheme was of course set aside.

5503. They went into Parliament after that attempt at legislation, did they not?—They did; the Act of 1852 was obtained, which was a compromise.

5504. You spurred them up to that state of activity?—We hope so.

5505. There was a general agitation, I believe, at that time, throughout the metropolis for an improved and constant supply of water?—There was.

5506. And there was considerable discussion as to the possibility of obtaining a sufficient supply from the chalk at Watford?—There was.

5507. Will you be good enough to describe to the Commission the general features of your plan which was before Parliament in 1849 and 1850?—It was proposed to take the water from the catchment basin of the Thames above Henley-on-Thames. The drainage area above Henley Lock is 2,500 square miles, or 1,605,000 acres, or equal to one-twentieth part of the area of England.

5508. When you speak of that area you mean that part of the Thames watershed west of Maidenhead?—Yes, above Henley and Oxford on the one side and the river Kennet on the other.

5509. Therefore it is above the point where you tap the Thames?—Yes, it takes in both the Loddon and the Kennet, but leaves out several of the streams which fall into the Thames below. The annual rainfall over this district is about 26 inches.

5510. How do you ascertain that?—We ascertained it from Mr. Blackwell, the engineer of the Kennet and Avon canal, who had very accurate gaugings made for

J. R. McClean, Esq.

27 June 1867.

several years, and the result was that the mean rainfall was estimated at 26 inches; of course it could only be an estimate.

5511. Do you remember the number of years that those gauges were down?—I do not, but I can give the whole of the gaugings if required.

5512. Were there a sufficient number, as far as your memory serves you, to give anything like a fair estimate of the amount of rainfall?—Yes, I believe so.

5513. And this is the mean of the several gaugings?—Yes, this is the mean.

5514. (*Mr. Harrison.*) Mr. Blackwell was for many years engineer of the Kennet and Avon Canal, and it was during that period that he had taken observations?—It was; and his father was engineer before him, so that he had very great experience. He was joint engineer with me in this project, but he is since dead.

5515. (*Chairman.*) You book 26 inches as the mean rainfall, and did you take any gaugings of the river at the point where you propose to tap it, or at any other point, so as to enable you to judge of the net result of that rainfall in passing any given point of the river?—Yes, we did. Mr. Blackwell, during one of the driest seasons at that time on record gauged the weir of the Henley reservoir or basin.

5516. Was it in a condition to enable you to make an accurate gauge?—Yes.

5517. Is it not very much out of repair?—Yes, very much, but it was in a sufficient condition to enable him to gauge. During the driest season not less than 345,000,000 gallons passed through the Henley Pond on any day. Mr. Blackwell states that quantity was the minimum of the gaugings, taken near the termination of an unusually long protracted season of drought, that was in the year 1848–49.

5518. How long after it has ceased raining is the effect of drought shown on the river by a diminished quantity of water?—It depends on the rainfall.

5519. Do you know whether the gauging at the Henley Weir was made a sufficient time after the fall of rain really to be called a dry weather drought gauging?—Yes it was. Both Mr. Walker who reported on the whole subject for the City of London and Mr. Leach adopted those figures.

5520. Some time after the rainfall the water will flow into the Thames in abundance?—Yes. If you will allow me I will read what Mr. Blackwell says about that. "Now over this district the average "annual fall of rain is 26 inches, of which experiment "has shown that one-half is evaporated or permanently "absorved, leaving a depth of 13 inches as the quantity "which passes down the river at Henley. This "total quantity we may expect, therefore, to be "75,751,983,450 cubic feet," or, on an average, 1,300,000,000 gallons daily.

"But it will be obvious that a very large portion "of this runs to waste in floods in the winter, and "the practical question becomes how much we may "expect to find in the river in any particular month "of the year; and the solution of this will depend "on the geological formation and the nature of the "soils of the district drained. If the soil is either "a hard rock, or impervious clay, the rain cannot "penetrate, and rushes off to the brooks and rivers "immediately on falling, accelerated or retarded, "of course, as the slopes of the hills are greater or "less. If on the contrary it is of a porous character "the rain water percolates slowly through, and it is a "long time before it feeds the streams. Now the "district which is the great receiver of our supply is "essentially of the latter character as the following "geological divisions in which I use Dr. Smith's "nomenclature will show."

		River Loddon.	Kennet.	Isis and Thames.

"In a geological point of view the river Thames is, "of all the large rivers of England, that in which we "may expect the slowest and most constant influence of "the rain that falls. From the basins of its tributaries, the rivers Kennet and Loddon especially, "consisting as they do almost entirely of chalk or "other pervious subsoil, the water finds its way very "slowly; and it is not until after many weeks of "drought that any diminution of the quantity "they supply is perceived."

"The results of my own carefully repeated "experiments quite agree with the conclusions that "a scientific consideration of the above data would "lead to. The volumes of the Thames at Henley, "as well as those of the Kennet and the Loddon, "have been repeatedly gauged, and the results "obtained lead me to the conclusion that at the time "of the shortest water the quantity passing the point "at which we propose to take our supply is not less "than 55,500,000 cubic feet, or 345,000,000 gallons "daily. This is the minimum of the gaugings, and "taken near the termination of an unusually long "protracted season of drought."

5521. Have you calculated the area and the number of inches that would give you that 345,000,000 gallons?—Each inch of available rainfall would give 100,000,000 gallons per day during the year.

5522. Then you would get not quite $3\frac{1}{2}$ inches?—It would be about $3\frac{1}{2}$ during the driest season.

5523. It has been calculated that you catch 5 inches out of a rainfall of 25 or 26 inches in the year?—13 inches was Mr. Blackwell's calculation. One half is lost by evaporation and absorption, and 13 inches passes down into the Thames; but if the flood water, as I propose, were saved by raising the levels of the different weirs, and canalizing the Thames in a more perfect manner than it is now, much more than 13 inches might be obtained, because during floods the water passes over and inundates the country, and a great deal of water is lost both by evaporation and by absorption.

5524. You mean that there would be no difficulty in storing, by means of reservoirs or otherwise, the flood waters in the upper districts?—In the Thames reservoir itself I should propose to store the whole of the flood water of the Thames. There are 2,000 acres of available area in the bed of Thames itself for storage, and what I propose is to canalize in a more perfect manner than it is at present the Thames, both

for the supply of water and for improving the navigation.

5525. Between each lock you would constitute the river a reservoir?—Yes, by means of embankments.

5526. Could that be done without inconvenience by flooding?—Yes, it would prevent floods. It would remove the inundations entirely. We should have to embank the Thames. In many places there is high ground on one side, but where it was required we could embank the Thames, and we could in that way get a storage for 5,000,000,000 gallons, equal to 25 days supply of London, taking 10 feet as the average depth over the 2,000 acres.

5527. Do you mean that the area of the Thames is 2,000 acres?—Yes, the area of the bed of the Thames alone above Henley is 2,000 acres.

5528. Would there be any difficulty in storing the storm water at a very much lower point than Henley for the purpose of feeding the Thames?—I do not know any place so convenient. Of course you might canalize it in the same way all the way down.

5529. But with regard to the several locks below Maidenhead, if those locks were raised a given height, you would store just in proportion to that height?—You might do so all the way down to the sea, but the object in taking the water at Henley is to take it from a pond on a level 105 feet above low water of the Thames, and obtain by gravitation a supply of 200,000,000 gallons a day without pumping.

5530. It would be possible, would it not, to adopt your view of intercepting the flood water above Henley for the purpose of giving you gravitating power to supply the higher parts of the metropolis, and at the same time to store the flood water at a lower point, and bringing it down to the metropolis for the purpose of supplying those parts which are not of the same height?—I have sent in a small section to your Royal Commission, on which (if you will be so good as to refer to it,) you will see the aqueduct and the levels of various places in London. The level that we propose for the aqueduct is the same as the New River Head in London, or about 100 feet above low water of the Thames at London Bridge.

5531. With regard to your high level, of course it gives you a greater head than if you were to take the water at a lower point?—It does.

5532. Will you describe the course of your aqueduct, and how you propose to carry it from Henley to the metropolis; would it be in open cutting?—It would be an aqupduct or canal 36 miles in length, but for the last five miles near London it would be covered; the width of the aqueduct would be 40 feet, and the depth 12 feet, having a fall of three feet or one inch per mile, which would be sufficient to deliver 200,000,000 gallons daily at the level of the Paddington Canal or the New River Head, 105 feet above low water of the Thames at London Bridge.

5533. In your judgment will that fall be sufficient?—Quite so.

5534. And that canal 40 feet by 12 with a fall of one inch per mile would give you a discharging power equal to 200,000,000 gallons?—Yes, at the level of the New River Head on the Paddington Canal.

5535. Is the open cutting of the same size all the way through, or does it increase in size as you approach the metropolis?—To bring the whole 200,000,000 gallons it would require to be the same size throughout, but within five miles of the metropolis I should propose to cover and divide it.

5536. Do you take in any other water in the course of your aqueduct than that which you catch near Henley?—In this scheme it was not proposed to take in any other, but the Brent might be taken in and the Colne from Watford.

5537. Then you would have it the same size throughout?—Yes, the estimate is for the same size throughout.

5538. Do you propose to line it?—It is proposed to be a regular aqueduct puddled the same as any canal, but not for the purpose of navigation.

5539. Would you line the sides with rubble or stone, or concrete?—It would be lined throughout, we should puddle the bottom and puddle the sides and line them when required.

5540. I presume that the fall of one inch would not interfere with you at all, with regard to the sides of your canal?—No, not all. The object is to deliver it as slowly as possible for the purpose of having the river water purified by allowing the materials in suspension to settle. The velocity would be under three-quarters of a mile an hour, so that the water would take about 48 hours to come into London from Henley Pond.

5541. Was your canal to proceed from near Henley to Hampstead?—Yes, you will see the site of the reservoir on the section.

5542. Is it on Hampstead Heath?—No, the main reservoir brings it in at the level of the Paddington Canal, where the first reservoir is shown on the plan.

5543. What height above high water will you be at the reservoir near to Hampstead?—105 feet above low water at London Bridge.

5544. You would require, would you not, to pump the whole of your water?—No, about five-eighths of London would be supplied from that level by gravitation; it is the same level as the New River Head.

5545. Would 88 feet head five miles off be sufficient to resist the friction and supply at the proper height?—It would be just the same as the New River is now. Whatever the New River will supply now, this would supply to the East End of London, and it would also supply Surrey. We proposed to make a reservoir on the Surrey side.

5546. From the reservoir at Hampstead, I see on your section, there is a line accross the Thames to Surrey?—Yes.

5547. Where is that reservoir to be?—At Clapham, supplied from the high level after having been pumped up to the Hampstead reservoir.

5548. How was it to be conveyed from Hampstead to Clapham?—Through pipes.

5549. Was it by gravitation?—By gravitation from the reservoir at Hampstead.

5550. Would your 105 feet be sufficient for that?—No. You will observe there are two reservoirs, the one close to the Paddington Canal, where it was proposed the pumping station should be situated in connexion with the Paddington Canal where coal might be obtained. The water at a level of 105 feet would supply all the low part of London, and the water for the supply of the higher part of London would be pumped from the reservoir at the Paddington Canal up to Hampstead Hill.

5551. Would that give you a sufficient head to bring it to Clapham?—Yes, to supply the whole of London. The object was to have the constant pressure and high service for the whole of London. The reservoirs since constructed by the various companies would, I believe, be sufficient for high service.

5552. What is the size of your reservoir near Hampstead?—It is not large, because the whole aqueduct would form a reservoir 36 miles long, and having a sectional area of 480 feet, and in addition there would be the reservoirs of Henley, and all the levels of the Thames above and beyond Oxford, in all upwards of 2,000 acres.

5553. Are there any other advantages than that of the head in taking the water so high up the river as Henley; why not allow it to flow down the river and take it at a lower point provided the impurities are intercepted, and the river is preserved from that pollution from which it now suffers?—There are other advantages in addition to the head of 105 feet which is obtained by taking the water from Henley. There is the purity of the water at Henley and the comparative excellence in quality.

5554. This plan of yours involves pumping; have you calculated the additional cost supposing you took the supply of water at a lower point in the river and saved the construction of this aqueduct?—The additional cost of pumping, including works, would be

J. R. McClean, Esq.

27 June 1867.

75,000*l.* per annum, but the same water could not be obtained either as regards purity or softness.

5555. Have you any other reason than that of the height of taking the supply at so high a point as Henley?—We found that the best point for the reasons stated in Mr. Blackwell's report, viz.:

"I will now speak of the *quality* of the water at the point where it is proposed to take it. It is well known how much this depends on the nature of the soil over or through which it flows. Thus some rivers which drain a country principally formed of magnesian limestone acquire a medicinal property, which renders them quite undesirable for a water supply. Others, again, flowing through a new red sandstone district, acquire a red tint which no filtration will deprive them of."

"Turning, then, to the soils drained by the rivers Kennet, Lodden, and Thames above Henley, I find them of the nature best suited for furnishing a pure and wholesome water. Indeed, looking at the vast area of chalk and porous sand and gravel in these districts, it is evident that the greater portion of the water is in reality *filtered*; that the rain falling over at least 800,000 acres passes through the porous subsoil of the uplands and comes filtering out in the valleys of the Isis, Kennet, and Loddon. The river Kennet, on which I have long been professionally engaged, is characterized by this peculiarity. Its total drainage is about 460 square miles, of which at least 400 are of this absorbent character, and the slopes of the land are generally so flat as to allow this filtering and absorbent character to take the fullest effect, as indicated by the unfrequency of floods, the regularity of the summer flow, and general purity and clearness of its waters."

"With regard to the chemical quality of the water of this district, analysis shows that it contains nothing prejudicial to health, but only the same inconvenience popularly called 'hardness,' which is peculiar to the water of that wide geological area occupying the south-east of England, and caused by the solution of the carbonates and sulphates of lime, which preponderate in the earth of that district. The analysis of the water of the Thames *above* the confluence of the Kennet shows the quantity of saline and earthy matter to be about $20\frac{3}{4}$ grains per gallon, and the quantity in the river Kennet to be only $15\frac{1}{2}$ grains per gallon, the relative hardness of the two samples by Dr. Clark's standard being in the Thames 18°, and in the Kennet 13°."

"Another influence on which the quality of river water depends is the number of towns and the proportion of the population to the area of its drainage. In this point of view the water of the Thames at Henley may be regarded as singularly pure. The average number of acres to each person, taking the whole of England, Wales, and Scotland united, is about $2\frac{8}{10}$, whilst the proportion in the area supplying the Thames above Henley and tributaries is as high as $4\frac{3}{10}$ acres to each person, showing the population to be thinner in this district in proportion to extent of country than in Yorkshire, Devonshire, or Cornwall, thinner, in fact, than over any equal area in any part of England."

"This fact will be better understood by recollecting that almost the entire drainage of the Loddon, the greater portion of the Kennet, and much of the Isis and Thames is derived from pasture districts, embracing the wide ranges of the Marlborough and Avebury Downs, the Vale of White Horse, the eastward slopes of the Cotswold Hills, the Ilesly Downs, Bagshot Heath, &c."

"Having glanced at the natural quality of the water dependent upon the soil, and the ratio which exists between population and area, there remains only to look at the nature of the manufactures and works established on the streams, for in proportion as these are of a delcterious character, so will the purity of the water be further affected. There are no manufacturing towns in the district. The mills above Henley are almost entirely used as corn mills, there being very few paper manufactures, whilst below Henley-on-Thames and tributary streams these become numerous and extensive. On the Wycombe stream, for instance, from that town to the junction with the Thames at Bone-end there are not fewer than 11 paper mills."

We had samples of water taken recently above and below the junction of the river with the Kennet, and we found the water below it better and more abundant.

5556. Can you give us an analysis of the water taken at that point?—Yes, I will hand in the analysis of the water taken both above and below the junction with the rivers Kennet and Lodden.

The witness delivered in the following paper:—

7, Quality Court,
Chancery Lane, June 1867.

SIR,

I BEG leave to report to you the results of my analysis of two specimens of water taken at your desire by my assistant on 28th May 1867, and marked as follows:—

"No. 1, taken from the Thames about 300 yards above Caversham Bridge, May 28th, 1867, 11.15 a.m. Temp. 57° F."

"No. 2, taken from the Thames below Boulney Court, Wargrave Marsh, May 28th, 1867, 3.15 p.m. Temp. 58° F."

Both specimens of water when viewed in bulk had a slight yellow colour, No. 1 being somewhat deeper in colour than No. 2. They are free from any unpleasant taste or odour. They also both exhibited a small amount of suspended matter, most likely occasioned by the agitation of the river by the wind, the day upon which they were taken being rather windy, but this suspended matter readily settled out of both on their being allowed to stand for a few hours.

The following is a Table of the results of my analysis in a gallon of each:—

	No. 1. Grains.	No. 2 Grains.
Total solid contents	24·16	23·20
Consisting of—		
Mineral matter	22·32	21·60
Volatilized matter by carbonization	1·84	1·60
Oxidizable organic matter contained in the above volatilized matter by carbonization	0·95	0·66
Degrees of hardness before boiling	15·2	15·0
Do. do. after do.	4·6	4·4

The mineral matter was found to consist as follows:—

	No. 1. Grains.	No 2. Grains.
Silica	0·88	0·80
Peroxide of iron	0·56	0·64
Lime, principally as carbonate	8·64	9·09
Magnesia	0·63	0·63
Potash	0·68	0·80
Soda	1·61	1·59
Ammonia	0·016	0·009
Nitric Acid	0·896	0·752
Sulphuric acid	1·66	1·22
Chlorine	0·15	0·10
Carbonic acid and loss	6·598	5·969

On comparing the above results, it will be observed that in many respects these waters are very much alike, but in all the most material points, namely, the oxidizable organic matter, the ammonia, the nitric acid, and the sulphuric acid, No. 2 water, is the best as containing less of these substances. The colour noticed when these waters are viewed in bulk would no doubt be removed by a proper filtration.

I remain your obedient servant,
(Signed) DUGALD CAMPBELL.

J. R. M'Clean, Esq., 23, Great George Street, Westminster.

5557. That analysis shows that the water is of a hardness not exceeding 15 degrees?—Yes, previous to boiling, but it is capable of being boiled down to 4·4. In looking over the report of the Government

Commission in the year 1851 I find that this water compares well with any other waters that had been sent in. (*The witness delivered in the report.*)

5558. (*Mr. Harrison.*) That was at the period when the companies took a great deal of their water lower down the river than they do now?—Yes, they took it at Vauxhall and some at London Bridge. It was before the water was taken above the tidal influence of the river.

5559. (*Chairman.*) What was to be the cost of this work?—The estimate was 1,500,000*l.* I have not gone into it recently, but of course during 20 years engineering has made great progress, and there may be great changes in the estimate.

5560. You would have to add, would you not, for the increased cost of labour and materials something like 30 per cent. between 1851 and this time?—I have not found much change in prices since that period, at least in the cost of executing the whole of a work. The price may have increased as regards a portion of it, but, taking it as a whole, work is now as cheaply done as it was 20 years ago. The application of machinery is so great and the improvements that have been effected, even in excavating, make work about the same cost now as then.

5561. But the price of labour has considerably increased?—Yes, but you do not require so much manual labour; machinery supplies its place, and keeps down the price of the work.

5562. Then concrete would be very much more expensive now would it not?—Lime is not dearer now than it was then, and there is gravel everywhere throughout the proposed work.

5563. Lime is dearer now than it was in 1851, is it not?—I think not.

5564. Is the 1,500,000*l.* of which you have spoken the cost of the aqueduct?—Yes, it includes the cost of the aqueduct, the reservoirs, and the raising of the Thames at Henley, but not the improving the river above Henley.

5565. When you speak of raising the Thames you probably mean raising the river?—Yes, raising the level of the river by means of embankments and locks.

5566. And does it include the cost of carrying the water from Hampstead Heath to the Surrey side of the river at Clapham?—Yes, it does.

5567. What was the additional cost of the loop across to Clapham?—It is included in the estimate.

5568. Referring to the cost, do you mean that the sum of 1,500,000*l.* is the structural cost, or does it include the purchase of land, easement, and severance?—It includes the purchase of land. The valuation at that time was made by Mr. Henry Hunt, and it includes machinery, bridges, and everything to bring the water into London and up to Hampstead.

5569. How did you propose to carry out your scheme in 1851?—By means of a Commission.

5570. (*Col. Harness.*) Did your estimate include the pumping for raising the water to the reservoir at Hampstead?—No, pumping above the level of 105 feet above the Thames would be an annual cost.

5571. (*Chairman.*) I understand that the structural work does not include even machinery?—It does. The estimate of 1,500,000*l.* is for the cost of aqueduct for its whole length, including reservoirs, and land, and compensation, and including iron mains and pumping engines and all contingencies.

5572. (*Col. Harness.*) Therefore, that would not put any water into the higher Hampstead reservoir?—No. It does not include pumping.

5573. (*Chairman.*) Can you shortly state the scheme that you suggested in 1850, whether it was to be carried out by means of a joint stock company or a commission and municipal authority?—At that time we proposed to have it carried out by a commission, but the termination of our work was the passing of the Waterworks Act of 1852 (*handing the same to the Commission*), which has settled the question up to the present time. The water companies at that time agreed to take the water above Teddington Lock and the question was practically settled.

5574. Will you shortly describe your own scheme?—I have nothing more to add, except as regards the areas of the catchment basins that have been suggested to the public. The Thames above Henley is 2,500 square miles, and will require only 2 inches of effective rainfall to supply 200,000,000 gallons daily. The area of the sources of the Severn are only 204 square miles, and will require 25 inches of effective rainfall, and from the Cumberland lakes 177 square miles, 28 inches of effective rainfall will be required for the same quantity. It is proposed that the surplus water not required for domestic, trade, or ornamental purposes, should flow daily through the Paddington canal and the various sewers which pass under it into the Thames; so that practically an arm of the Thames, 105 feet above low water, would be continually cleansing the metropolis.

5575. Has anything occurred in the government of the metropolis since that period to cause you to alter your scheme with reference to the authorities to carry it out?—Yes, the constitution of the Metropolitan Board gives facilities now for carrying it out in a better way than proposed at that time.

5576. Are you of opinion that the supply of water should be in the hands of a municipal body as a principle?—The supply of water I think ought to be in the hands of a municipal body, but the distribution of the water to the houses, the collection and all the details ought, I think, to lie in the hands of a water company.

5577. Do I correctly gather from your answer that you would constitute the municipal authority the wholesale dealer in water, and that they should contract with parties to distribute that water from a given point?—Not exactly so. The mode that I propose is for the Metropolitan Board to make the aqueduct and the Thames Conservancy to execute the works, to improve the navigation, and to store the water in ponds.

5578. That is to say, the works on the Thames?—Yes, the works on the Thames simply. That the Metropolitan Board should make the aqueduct which should afford the means of supplying London with fountains, watering the streets, in fact every purpose of that kind, or for giving it to the dwellings of the poor unstinted, and that arrangements should be made with the present water companies who have had great experience in the distrbution, so that they should have the water at a level of 105 feet above the Thames to distribute. That would save a great deal of pumping and their present machinery by merely being removed to that point would come in for the high service of London, so that nothing would be lost.

5579. (*Col. Harness.*) Would you have two sets of distribution pipes over the same district, partly in the hands of the company and partly in the hands of the Metropolitan Board?—Yes, you would have additional pipes, you would not disturb the present pipes that belong to the water companies, but you would have additional pipes for watering the streets, the same as in Paris; they have two supplies there, one is from the Seine and the other from the Canal de l'Ourcq for the streets, for all municipal purposes and for fires, which do not interfere with the house supply. In Paris at the present time every street is constantly being watered. The supply is so abundant that to waste water is impossible.

5580. (*Chairman.*) Would not it be a serious question to duplicate the network of pipes in the metropolis?—I should think not if it is only for public purposes for hydrants, for fountains, and for fire.

5581. Would you propose to have a second pipe in every street in the metropolis or in the principal streets?—I have not gone into the details but it has been very well carried out in Paris where they have two supplies without any difficulty. There the pipes are carried in subways and it is quite immaterial whether there are one or five sets of pipes.

5582. (*Col. Harness.*) Therefore their repair does

J. R. McClean, Esq.

27 June 1867.

not necessitate the removal of the surface of the street?—It does not.

5583. (*Chairman.*) Do you see any practical difficulty in the municipal authority carrying out those large works, bringing the supply of water from a distance, constructing the aqueduct and reservoirs, and then letting it to parties for the purpose of distributing the water amongst the inhabitants?—I see no difficulty.

5584. What is your special reason for stopping the action of the municipal authorities at the end of your aqueduct?—Merely on account of the experience of the present companies. It might then be under municipal regulation, but my object was to interfere as little as possible with the present piping and works of the various companies, but I see no reason why they ought not to be under municipal management.

5585. Supposing arrangements were to be made with the several companies would it not produce more harmony of control over the general distribution of the water if the whole thing were under the management of one body?—If there were no difficulties in making the arrangements I believe it would be so.

5586. Then it was to save the present several companies their pecuniary interests that you suggested this special arrangement?—It was, and because there was no machinery at that time to carry out any other system.

5587. Have you turned your attention to the question of the constant as compared with the intermittent supply?—I have.

5588. What is your opinion upon that question?—I have adopted it upon a very large scale in Staffordshire, and the whole of the district between Burton and Dudley, and even beyond as far as Brierly Hill, a length of nearly 40 miles, is under high pressure and constant service.

5589. Do you mean the several towns in what is called the Black Country?—Yes, the district comprised in the supply is marked in this map (*handing in a map to the Commission*). We are now proposing to carry it further to Birmingham and to make it all one district.

5590. Are you the engineer to those several towns?—In South Staffordshire for the towns shown on the map I am, and I have been from the first.

5591. Do you take your supply from one source or from several sources?—From one source. At the present time we take it entirely from the new red sandstone of the Permean measures.

5592. Do you obtain a sufficient supply for the several towns for which you are engineer?—We have not been obliged to resort to any surface water. The company are pumping now 4,000,000 gallons a day and distributing it over the district which you see on the map; they have facilities for collecting an almost unlimited quantity of water running down from the high land of Cannock Chase if it should become necessary to resort to that source hereafter.

5593. Is 4,000,000 gallons per diem equal to supply all those towns in the Black Country?—At the present time it is, but we have the means of giving 10,000,000 gallons more.

5594. What quantity of water per head do you allow per diem?—We allow an unlimited supply.

5595. What is the consumption per head for domestic and manufacturing purposes?—I do not know the number of persons supplied.

5596. Have you formed any distinct idea as to the proper quantity for the metropolis, including manufacturing purposes?—I think it ought to be unlimited. There ought to be no restriction on the supply.

5597. What quantity per head would, in your judgment, be an abundant supply for all purposes, domestic, sanitary, and manufacturing?—There is great difference of opinion. In Staffordshire, where the supply is unlimited, and where there are so many large works, and where the water is continually laid on, the supply is only 11 gallons per head for the entire population, but I do not know how many use the water.

5598. Are we to understand that all the towns in the district coloured on this map which you have handed in are supplied on the constant system?—They are.

5599. How long has it been in operation?—About seven years.

5600. Were you the engineer prior to the adoption of that principle?—I was the engineer who suggested the whole scheme. Those towns had no supply of water except from the canal.

5601. Speaking from memory, can you state whether the application of the constant system has led to a waste of water or to economy?—We never had any system except the constant system; the works were constructed for the constant supply and high service.

5602. Therefore you have no means of contrasting the two systems?—No, except that we know what the cost of the water is, and we know what the water rents are.

5603. Speaking generally, are you of opinion that the constant supply system is the proper one?—I have no doubt of it.

5604. Can you state your reasons for that preference?—They are partly sanitary. Since that system was adopted the health of the people has improved very much in that district. There was not a single case of cholera during the recent outbreak in the district supplied from Lichfield, where we pump the water out of the sandstone.

5605. How did the poor people store their water prior to this system?—In all kinds of vessels. The women and children were constantly employed in the Black district in getting water and wrangling about the wells.

5606. The receptacles, I presume, were filthy in some cases?—Yes; at the present time the supply costs 1*d.* per ton; that is the charge made.

5607. How many gallons would that be?—224 gallons; it is cheaper now for them to take water into the houses by means of the waterworks company than to take it from the door if it were placed there gratuitously.

5608. How are the arrangements made for the supply of the houses of the poor; is it by means of standcocks?—No; a tap in each house is what I have tried to get everywhere.

5609. Have you found any difficulty in maintaining those taps?—None whatever.

5610. Have they been stolen or destroyed?—No, with few exceptions.

5611. Have you any special powers in your Act to superintend and inspect, or to punish parties for interfering with the taps?—We have unusually large powers of inspection, but we have seldom had to exercise them.

5612. Have you the means of detecting any serious waste in any part of the district?—We should detect it immediately.

5613. I mean on the works; could you detect it by any gauge constantly in action?—Yes. Whenever we suspect any consumer or any company of taking more water than they pay for, we put a gauge on the pipe going into their works, and ascertain the exact consumption.

5614. Are the large consumers supplied by means of a meter?—Yes, the very large ones are.

5615. At what rate per 1,000 gallons did you charge them?—The average is 5*d.* per 1,000 gallons, and the charge for the whole district, including everything, is 4½*d.*

5616. Then, of course, in preparing your mains and distributing your pipes, you gave to them a sufficient capacity to resist the pressure, and adapted them to this system which you have adopted, namely, that of constant supply?—Yes, the works were commenced on the high pressure system.

5617. Have you found any difficulty from breakage in any district?—None.

5618. Could that system be applied to the pipes which you are aware that we have in the metropolis?

—I have not sufficient knowledge of the pipes to know.

5619. In the case of pipes which have been long down, and are partly oxydised, it would be necessary to renew them before you could apply the constant pressure, would it not?—Not in London; we have a high pressure you may say now, but an interrupted one. The houses here 40 feet high have water to the tops of the houses, but it is only admitted for about two hours a day, so that the pipes would not require any additional strength.

5620. If you have the full strain on, and a pipe will resist that pressure for two hours, would it not resist the same pressure for 24 hours?—Yes, certainly.

5621. As far as the application of the constant system to the metropolis was concerned, it would simply have reference to the internal arrangement of the pipes for closets and other purposes?—Yes, it would, and getting rid of cisterns.

5622. Have you any special tap that you use in your district?—Nothing but the ordinary screw tap.

5623. And is that found sufficient?—Yes.

5624. How do you arrange in cases where the better houses in the district have waterclosets?—They are put on direct, with a small cistern containing merely a few gallons, but there are only a few large cisterns I believe.

5625. Then it is simply a catch basin?—Yes, some little arrangement of that kind.

5626. Immediately that basin is emptied it is refilled by the constant pressure?—It is.

5627. And that cuts off any communication of gases from the closet to the water?—Yes, it does.

5628. And that is a very small affair?—Yes, very small.

5629. Have the poorer classes closets?—The poorer class have not closets in Staffordshire; they generally have privies outside.

5630. And the night-soil is removed?—Yes, but the higher class have closets now; formerly they were not able to procure them on account of the expense and want of water.

5631. With regard to the poor would you deal with them in the same way as you do with the class of persons that you have described, by giving them a watercloset with a small cistern for the immediate use of the closet?—Yes, and so I would give them an unlimited supply.

5632. Have you any cases where there is simply a tap into the main, and by turning the tap the water is turned off from the main?—None into the closets, but into the houses. The water comes direct from the main.

5633. Would it be objectionable in your judgment to have a tap liable to be left running into a closet and wasting the water?—The objection is more imaginary than real, but one would not like to recommend it.

5634. But looking at it as a whole, you see no difficulty in the application of the general principle of a constant supply?—I do not.

5635. Do you think that sanitary regulations would be considerably promoted by the application of the system?—Yes.

5636. And having regard to the purity of the water and the freedom from those contaminating influences resulting from imperfect storage, do you think that the health of the people would be improved?—I believe so, besides the economy is very great. By steam power water is taken to the top of a house 40 feet high for 1*d.* per ton, it is a most economical mode of raising water.

5637. Speaking generally of the Thames watershed, are you of opinion that it is possible to catch a sufficient quantity of water to supply the metropolis now and for many years hence?—Yes, by storing the flood water in the upper reaches of the Thames as I have described I have no doubt that you may obtain more than any quantity that can ever be required.

5638. Then you think it unnecessary that the metropolis should seek for a supply of water from wells or from the lakes, or from any distant point?—I do. In the paper which I have handed in, the report of the former commission analysing the water of London, they go particularly into that point about the wholesomeness of the Thames water, and they say that none of the salts that are in it are at all injurious to health, the only difficulty is about the quantity of soap that is required.

5639. Has your attention been directed to the question of the use of soft water as compared with water of 15 degrees of hardness and its effect upon health?—It has to a certain extent. I am engineer to the Eastbourne waterworks, and when I became their engineer the supply of water was from the chalk. I induced the Duke of Devonshire who is the principal person there to pass through the gault down to the green sandstone in place of taking the water from the chalk. There is an abundant supply from the chalk, but the water from the green sandstone is very much superior to the water from the chalk, and now the town which is a very important and rising one is supplied by constant service.

5640. What is the degree of hardness of that water as compared with the water previously used?—The Eastbourne chalk water is $13\frac{1}{2}^{\circ}$ (Clarke's scale). The Eastbourne green sand water is 8° (Clarke's scale). In Staffordshire the water is from the Permean measures, but we find no difficulty on that score, it is all good water, and is 8° of hardness (Clarke's scale).

5641. In your opinion is water of a moderate degree of hardness better for the health of human beings than soft water?—I believe it is. People are obliged to go to watering places for the purpose of getting salts; but for general purposes it depends on the nature of the hardness, and whether it is temporary hardness, which may be softened by boiling, or hard from constituents which cannot be removed by that process; or sulphate of lime, which renders the water unfit for culinary purposes.

5642. Does that apply to cattle?—Without giving a medical opinion I believe that the more salts there are in a water the better for the human system, excepting some of the objectionable ones which are mentioned in the report containing nitric acid and one or two other salts.

5643. (*Mr. Harrison.*) You stated that out of a rainfall of 26 inches you calculated that 13 inches would be available?—Yes, if required.

5644. We have had evidence before us based upon observation extending over at least 11 years which shows that the actual quantity discharged in the Thames does not average more than one-third of the rainfall, that is to say, eight inches?—Yes, I have no doubt that there is a great difference in different districts.

5645. But taking that which is discharged at Teddington Lock it amounts to one-third of the average rainfall which is about 26 or 27 inches. Supposing that you were to take the water as you propose from Henley, should you not have to make some provision for the remaining portion of the Thames below that point to keep it with a sufficient supply of water in it constantly?—Yes, by storing the water in the reservoirs I have referred to you may have a quantity of water constantly running over the weir below Henley nearly equal to the supply in seasons of drought.

5646. So that by your scheme you would never reduce the quantity say at Windsor below its present minimum volume?—Quite so.

5647. (*Chairman.*) Do you mean that you would never reduce the water level?—I believe there never would be less than 300,000,000 gallons passing over the weir at Henley.

5648. (*Mr. Harrison.*) And that you would obtain by raising the banks of the river at the different locks, in point of fact canalising the river and converting it into a reservoir?—Yes, of an area of 2,000 acres.

5649. (*Col. Harness.*) And a depth of 10 feet?—Yes, and an average depth of 10 feet.

5650. (*Mr. Harrison.*) You mean not only that you would keep the surface level of the water of the Thames below Henley at the same level as it is now,

J. R. McClean, Esq.

27 June 1867.

but that you would actually allow from the reservoirs above Henley the same daily quantity of water to flow as a minimum flow into the river below Henley as does now?—That is so.

5651. Do you think that since the period of your estimate you would not find a large increase in the value of land, particularly at Hampstead where your reservoir would be?—That may be so, I have not gone into that; Primrose Hill was the place for one reservoir.

5652. Excepting the value of the land you are of opinion that things would remain the same?—Yes.

5653. There is one important question which arises out of the system of the South Staffordshire Waterworks which I should like to ask you about. This is almost the first case, is it not, in which the towns in a large district of country have been grouped together under one system of supply?—It is.

5654. The population, excluding Birmingham, included within this district is about 400,000, is it not?—Yes.

5655. Do you think that you are now supplying the whole of that population of 400,000?—No. It requires a considerable time for a waterworks to attain its maximum.

5656. Can you tell what proportion of that 400,000 is supplied?—I cannot.

5657. I ask that question because I see that your present quantity is only 4,000,000 gallons a day which to supply a population of 400,000 would be equal to only 10 gallons per head?—It is more than that at the present time, that is assuming the whole district to be supplied.

5658. At present you derive the whole of your water by a tunnel which you have drifted into the red sandstone?—We do.

5659. And by additional tunnels at different places into this red sandstone of the Permean measures you would expect to get a much larger supply if necessary?—Yes.

5660. Do you think that it would be advisable to adopt the same principle of grouping districts in other parts of the country as you have done in Staffordshire?—I think it would be very desirable where you have a quantity of water suitable and available for household purposes.

5661. Do you think it would be desirable when water companies are seeking powers from Parliament, say for one large town, that they should at the same time be under an obligation to supply any adjoining small towns in the district?—I think it would be very desirable if the small towns agreed to pay for the same.

5662. By combining, as you have done in this case, to a large extent, do you not think that you would be justified in going to a larger outlay than you otherwise would do?—I think so, that would be the most economical way of doing it.

5663. And by enforcing such a rule the general public would in the end be much better supplied than they otherwise would be?—Undoubtedly, and with much purer water.

5664. By your Act of Parliament you take power to supply all those towns?—We do.

5665. And you are at the same time under the obligation to supply them?—We are. Under the General Waterworks Act we are obliged to give a supply when the pipes are in a certain district, or if the householders are willing to pay 10 per cent. on the cost of putting a pipe in a particular street. You will find under the General Act that there is no compulsory clause beyond that.

5666. Are there not a great number of cases in which that General Act really would hardly apply?—There are.

5667. (*Chairman.*) When you say that the householder has to pay 10 per cent. do you mean that 10 per cent. is to be paid by the householders in a street?—The aggregate householders have to pay 10 per cent. upon the cost of the pipe.

5668. (*Mr. Harrison.*) Excepting in cases where you are within a reasonable distance of a town, that provision would be entirely nugatory?—Yes.

5669. And in many cases I daresay you will find that there are large towns and villages which you have not supplied at all?—There are a few. We already supply Burton and a portion of Lichfield, Walsall, Wednesbury, Bloxwich, Brownhills, Pelsall, Rushall, Darlaston, Tipton, Great Bridge, West Bromwich, Oldbury, Smethwick, Handsworth, Dudley, Rowley Regis, Ledgley, Kingswinford, Brierley Hill, The Lye, Halesowen, Streethay, and several other towns in the district. We have not got the pipes to Tamworth yet, but the corporation there have the matter now under their consideration.

5670. Do you know the area of the present district which you supply?—The area is 250 square miles, and the total population is about 400,000, and negotiations are now being carried on between the Birmingham Waterworks Company and the South Staffordshire Waterworks Company to put the whole under one management, and Wolverhampton may eventually be under the same, so that there may be a population of upwards of 1,000,000 supplied from the same source. The water is pumped from Lichfield to the summit, 200 feet high, to reservoirs in the Black District, about 200 feet above the average level of the towns.

5671. (*Mr. Harrison.*) I gather from your views that the principle which you have adopted is a sound one to apply generally when water companies are getting their Acts of Parliament?—Yes, when you get a pure source. My attention was called to that subject some years ago with regard to the supply of Hastings. I advised them to get their water from Eastbourne, as the nearest point where the lower green sandstone occurs, in order that they should take a supply from inexhaustible sources.

5672. Arguing from what you have done yourself at Eastbourne, and what you have done in South Staffordshire, it is obvious that you prefer a soft water to a hard chalk water?—Yes.

5673. Generally, is not the water of the Thames at Henley very much the same in character as the water which you would get at Eastbourne from the chalk springs?—No, the chalk formation occupies less than a quarter of the Thames basin above Henley.

5674. Then at Eastbourne you have thought it desirable to go to a better source of supply?—Yes.

5675. That would lead to the conclusion in your mind that if you had had a choice between a hard or a chalk water, as in this case, and soft water, you would prefer the soft water?—People do prefer it. I myself prefer hard water for drinking if it is free from deleterious salts, but for many other purposes soft water is the best.

5676. You have suggested that the Thames Conservancy are the proper parties to bear the cost of constructing the works of the embankment of the Thames above Henley?—To carry out the works.

5677. How would you remunerate them for the outlay?—A portion of it, of course, would be borne by the metropolis, because it would be for storing water for their supply, and a portion from mortgage of tolls, and from the land irrigated and drained.

5678. Then you would merely put the execution of those works in their hands because they are conservators of the Thames?— Yes, because they are conservators of the Thames now all the way up to Oxford.

5679. But you would have to find, would you not, some public body who would furnish them with the means of doing it?—Yes, the Metropolitan Board. It would not be very expensive, and a great portion of it would be repaid by the landowners. From the acreage which might be irrigated, and from which the floods would be entirely removed; the amounts derived from those two sources would form a very important income.

5680. The Thames Conservancy Board, under the Act which they have obtained, are now going to embank some portion of the Thames, are they not?—I

believe they are; but there are places above Henley which are capable of great improvement, and of affording a very valuable area for storage.

5681. (*Chairman.*) You suggested the Thames Conservancy Board as the proper parties to carry out the works in the river probably because they have exclusive jurisdiction over it?—Yes, they must always have it for navigation purposes.

5682. But the works which are to be carried out for the purpose of storing water, or for facilitating the storing of water, being for the benefit of the general public, should be paid for, should they not, by the public, and not out of the funds of the Thames Conservancy navigation?—Not altogether. They would be carried out for navigation, irrigation, removal of inundations, and drainage, in addition to the supply of water to London.

5683. You have referred to the scheme of the South Staffordshire Waterworks Company as that of grouping several towns together in a supply from one common source, by means of a joint stock company; do you see any difficulty in grouping the large towns in the north, between Leeds and Lancaster, or other parts, giving a representative body a control over the water, and each town in proportion to its population being represented on one central board for the management of the water supply of the several towns?—I have not gone into the question sufficiently to give you an answer. On the face of it I see no objection.

5684. Supposing one gathering ground could be used in common for all, and one aqueduct could be made equal to the supply of all, would it not be consulting economy as well as possessing other advantages to have a joint central board to manage the water supply, each town paying its proportion?—I believe it would.

5685. And that in your judgment would be a better arrangement than towns seeking an independent water supply for themselves from sources that might not be so good as some distant gathering ground, which if united they could obtain their water from?—Quite so. In many cases you might get water locally better than by aggregating the towns in that way, but where you have a good and an unlimited source of supply, I believe it is the best way of supplying a number of towns in England. This supply, which I have referred to, might be taken in Stafford and the Potteries where they are very badly off for water, and I do not know where they are going to get it. You might have any quantity of storing ground at Cannock Chase, which is the backbone of England. Both the subterranean water and the surface water are undoubtedly good, and I think it should be made available for Derby and a great many other places which are badly supplied at the present time, but it requires some time to carry it out; it is the only pure source there is.

5686. Has not the time arrived when the question should be fairly looked at as to preserving the gathering ground for the supply of water to the increasing population of those manufacturing districts?—I think it has, and also for preserving the subterranean supply.

5687. The local supply in many cases is becoming polluted, is it not?—It is. The subterranean supply is a more certain supply than the drainage areas in certain geological formations.

5688. (*Mr. Harrison.*) Have you found any diminution at all in the quantity of supply at any period of the year to your tunnel?—None whatever. We have made repeated experiments extending over 10 years. We have bored holes at different places in the tunnel to facilitate the flow of water from it, and I have put a pipe into those bore-holes, and I find that the water rises up in the pipes to exactly the same height that it did 10 years ago. There is not the thickness of a sheet of paper difference between the level of the water when it is pumped now and the level of the water 10 years ago.

5689. Are you aware that in the case of Liverpool where they take their supply from the red sandstone they lowered the level of the water at the place where they pumped from?—I have heard so. I read the controversy about it many years ago, but that is not the case in Staffordshire. It appears that after it rises to a certain level there is some subterranean overflow to the Trent, but up to this level it always rises to that level; the sources seem to be quite inexhaustible.

5690. What is the population of Birmingham?—About 350,000.

5691. If you were to add Birmingham to the present district which you supply you would get in the whole a population of 800,000?—We expect 1,000,000 at the end of two years.

5692. Taking the consumption at 30 gallons per head, which is now generally taken as the calculation, you would require 24,000,000 gallons per day, or just six times your present quantity?—No. We have now 10,000,000 gallons a day.

5693. Do you think you will have a sufficient supply by additional tunnels collecting the surface water?—Yes, I have no doubt of it, even without storing the flood water.

5694. You think that you could supply 24,000,000 gallons from the Permean formation?—Yes, by driving tunnels. Sinking shafts we find of very little use, the shaft only drains a certain area about the base, but the water does not filter through, it comes through in chasms, and you must drive a heading to cut those fissures.

5695. (*Chairman.*) You drive a shaft into the hill, do you not?—Yes, and cut the different fissures, and then the water comes through those fissures like springs, but you cannot get any supply from mere shafts.

5696. You have not only a shaft driven into the hill, but you have perpendicular openings, have you not?—We first sink a shaft and then drive a heading from it through the sandstone.

5697. And that of course cuts all the fissures?—Yes.

5698. (*Mr. Harrison.*) The tunnel which you have in this case is about four miles long, is it not?—Yes.

5699. (*Col. Harness.*) What guided you in the direction which you gave to that tunnel?—The geological map.

5700. With reference to what did you choose your direction?—To keep as much as possible in the one rock from which we found the best water. The pumping station is at Lichfield, and in the part marked F 5 on the geological map we find the purest and best water. The tunnel has been driven along the road to intercept the water. There is a fall of 800 feet which cuts off the communication between the coal district and the Permean formation, and we find that wherever we drive in F 3, F 2, and F 5 we get good water. In F 6 is bad, both the surface water is bad and the subterranean water is bad.

5701. Therefore you went as much as you could through F 5?—Yes.

5702. (*Chairman.*) How many sources have you?—We have only one channel.

5703. Have you more than one well?—No, only one.

5704. And that is found sufficient?—Yes, with the tunnel.

5705. Then you cut the fissures down to a given point, and you carry the channel along, conveying the water?—Yes. It is now under consideration to carry out the same system and make a tunnel between Lichfield and Birmingham, which will be 12 miles long, and it will cost about 80,000*l.* We shall get a supply from the high ground at Sutton Coldfield and all that district.

5706. What evidence have you now to satisfy you that you can increase your supply of from 400,000 inhabitants to 1,000,000, and give them a more abundant supply than they have at present; what evidence have you that this source will be equal to that?—We have now 10,000,000 gallons per day, and we find that for each mile of tunnel we generally get 1,000,000 gallons.

J. R. McClean, Esq.

27 June 1867.

5707. Have you observed any diminution in the quantity in any part of the year?—None whatever.

5708. Do you find that neither a rainy season nor a drought has any effect upon this storing source?—No, because we are still so far within the capability of our sources.

5709. (*Col. Harness.*) With your present arrangements, an overflow arises when you have not been pumping as much as you can take up?—Yes, it does.

5710. (*Mr. Prestwich.*) You state that the length of tunnel at present existing at Lichfield is four miles; do you find that it has had any effect upon the delivery of the streams in the district?—None that we have observed. The brook which formerly was used by the company, but which is now abandoned on account of the great subterranean supply, delivered 1,000,000 gallons daily, and we have found no change on account of the tunnelling.

5711. What depth is the tunnel?—It varies from 20 feet below the ground to 150 feet, all in the sandstone.

5712. Then, in the same way, you might, by a tunnel of that description, intercept the water in any district where the rocks are fissured and which abound in springs; for example, supposing there is a large flow from the chalk above Henley and Pangbourne into the Thames, do not you consider that by an intercepting tunnel of that description you would intercept the springs before they reach the Thames, and secure a supply of spring water of perfectly pure quality?—I do, and I am also of opinion that if a tunnel were driven towards Guildford, into the green sandstone, a very large quantity would be obtained; whether it would be sufficient for London it is a difficult question to answer, but a very large quantity of pure water might be obtained from the green sandstone.

5713. (*Chairman.*) What is the size of your drift?—It is 4 feet 6 by 3 feet 6.

5714. How is it sustained?—It is all in rock.

5715. (*Mr. Harrison.*) Did you make any experiments with regard to the delivery of the springs into the Thames from the chalk above Henley and Goring?—I did not myself, but Mr. Blackwell refers to it in his report.

5716. For how long a period were the gaugings of the river continued at Henley?—For many years in the Kennet.

5717. And what did you find to be the maximum flow at Henley?—The minimum was taken, not the maximum.

5718. What did you find it at Henley?—345,000,000 gallons, but that would be very much increased by the embankment preventing the water going out upon the lands and inundating them, where a great deal is lost both by evaporation and by leakage.

5719. That would put a stop altogether to the flooding of the meadows?—Entirely; it would irrigate them, not flood them.

5720. But at present that is a source of impurity to the river?—Yes, a very great source.

5721. And is it likely to become more so as the system of disposing of the sewage of towns is brought into operation?—Yes; but at Henley we got rid of nearly the whole of the sewage of the population on the Thames which could injure it. The sewage from Reading was intercepted, and the only towns of any importance above were Oxford and Abingdon. Those we proposed to get rid of in the same way by forming embankments and having side cuts, and having separate drainage for those towns, so as to render the Thames as pure as possible.

5722. For how long a period would the river, looking at it as a reservoir, suffice for the supply of water to London?—For 24½ days at 200,000,000 gallons a day.

5723. You stated that the soft water from the green sandstone was preferred to the water from the chalk at Eastbourne,—where was the water from the chalk obtained?—From springs.

5724. Not from wells?—No, from springs.

5725. Have you any analysis of that water?—I have.

5726. You are no doubt aware that the waters from chalk springs differ very materially?—Yes, I believe so.

5727. Did I understand you to state that you thought that the water at Eastbourne was similar to that of the Thames?—The chalk formation occupies less than one quarter of the Thames Basin above Henley. We find at Eastbourne that taking the water from the greensand, even within a distance of 200 yards, does not affect the chalk springs in the slightest degree; the galt between the two separates the waters completely, and, although there is a spring within 200 yards of the pumping station, our pumping at a depth of 75 feet does not reduce; the water in the chalk spring has never been reduced.

5728. Are those chalk springs still used?—The chalk springs are used for irrigating the marshes.

5729. (*Chairman.*) Are there any wells near to the stone which you are tapping at Lichfield, and if so, what has been the effect of your arrangement upon those wells?—We have been obliged to deepen the wells to the level of the water in the tunnel.

5730. Have you reduced the water line considerably?—No, we have not reduced it, but the wells were not down to it.

5731. Your pumping at the lower level had a tendency to draw the water from the upper level from whence the wells were supplied?—Yes, it did so until they deepened their wells to the same level as the tunnel.

5732. Then the water line must be lower?—The water line in those wells would, but we got the permanent water level when the tunnel was made, which has never altered since.

5733. But all sources of supply short of the level at which you are taking the water have failed?—They did until they sunk their wells deeper. We dried every well in the town of Lichfield during the construction of the works.

5734. (*Mr. Prestwich.*) Do you think that the local supply of Birmingham and the district around Birmingham is such, or could be rendered such, as to make it unnecessary to go to a distance for a supply?—I do, by extending the tunnel from Lichfield, and without taking any of the water of the river Tame, which now passes through Birmingham.

5735. Therefore, there being a supply near at hand, that would be the most economical supply?—Undoubtedly.

The witness withdrew.

J. Thorpe, Esq.

JONATHAN THORPE, Esq., examined.

5736. (*Chairman.*) You are deputy chairman of the Thames Conservancy Board?—Yes.

5737. The Lord Mayor is the chairman of that board is he not?—Yes.

5738. And you are the acting chairman?—Yes, the Lord Mayor of London is *ex-officio* chairman.

5739. As chairman of that board, of course your attention has been directed to the condition of the river?—Yes.

5740. And also to the source of the supply of water to the metropolis?—Yes.

5741. The several companies, I believe, are taking about 5,000,000 gallons now?—About 50 millions.

5742. They have a statutory right to take double that quantity, have they not?—I think so. They have by agreement with the corporation power to take 20,000,000 gallons each.

5743. The companies have power under the Act of

1852 to take 100,000,000 gallons in all from the river at the point at Hampton where they take it now?—Yes, I am not quite sure whether the quantity is limited by Act of Parliament or by agreement. I think it is by agreement.

5744. Is that an agreement with the Thames Conservancy?—With their predecessors the Corporation of London.

5745. Was that agreement confirmed by the Act of 1852?—I think so.

5746. Have you observed, as chairman of the Thames Conservancy Board, any evil effects from the abstraction of water from the river?—No.

5747. Are you of opinion that the quantity referred to, namely, 100,000,000 gallons, might be taken per diem without injuring the river as a navigable stream?—Yes, from all that I have learned, I think so.

5748. Do you think it would be prudent to go beyond that quantity?—I think if certain alterations were made in the river, and certain works executed, that quantity might be exceeded without injury to the river.

5749. When you say certain works executed, do you mean works for the purpose of storing water?—Yes, for the storage of water.

5750. You mean the storing of that which would otherwise run off in flood?—Yes, which would otherwise pass from the river. I rather wish to make a few remarks with reference to the upper part of the river, the part above Oxford.

5751. Is not that beyond your jurisdiction?—No, we have jurisdiction 46 miles from Oxford to Cricklade, under the Act of last year, and it is upon that part of the river that I wish to make a few remarks. I may say that little or nothing has been done to store the water, or keep up the head of water in that part of the river, and occasionally there are very heavy floods which are very damaging to the landowners on both sides of the river; indeed an extent of land, we will say from 20,000 to 30,000 acres, is yearly impoverished and damaged by the flooding of the upper part of the river, and the landowners of that part are very willing to contribute to the deepening and otherwise improving the channel of the river and embanking the sides where necessary. That land now lets at sums varying from 10*s.* to 15*s.* an acre, and if the land ceased to be liable to those floods the probability is that it would be increased in value to 2*l.* an acre, so that the owners and occupiers are willing to pay a reasonable sum towards the improvement of the channel of the river in order that floods may be prevented. That improvement and deepening could only be carried out by a system of dredging from Oxford upwards, 46 miles. If the river were to be so dredged, and in places widened, you would have as fine a store for water as you could desire. The landlords would be benefited, and instead of the water being occasionally polluted by stagnant water from land drainage, the quality of the water would be improved, and you would have an increased and a more regular supply. The expense might be defrayed by a contribution from the water companies, and by a rate upon the landowners, who have said that they are perfectly willing to pay, and are most anxious to see such works executed as would relieve them, and by an annual contribution from the barge traffic at either end of the district. A sum might be thus obtained which would enable us to improve that part of the river without distressing anybody, I mean a sum moderate in amount.

5752. I understand that your view is, that the 20,000 or 30,000 acres which are now subject to periodical flooding, and let at the low rent of from 10*s.* to 15*s.* an acre, if freed from those floods, would probably be worth 40*s.* per acre?—Yes.

5753. And the landowners are therefore greatly interested in embanking the river and deepening the channel?—Yes.

5754. And if in conjunction with the landowners, the water companies, and the Thames Conservancy Board, supposing they improve the navigation, were to join together, the river might be greatly improved, increased storage might be obtained, and a large area of land redeemed for agricultural purposes, and with very great advantage to the locality, and to the country generally?—Just so.

5755. Have you formed any idea of the cost of that embankment which would be necessary to exclude the flood waters from the adjoining land?—Most likely the dredging and such arrangements as might be deemed necessary over the 46 miles if that were required (it would not be required in all parts) would amount to from 200,000*l.* to 300,000*l.*; but the work could be only executed gradually.

5756. Do you mean that the dredging would cost that, or the dredging and embanking?—The dredging and embanking, but it could only proceed by degrees, and probably a contribution of something like 12,000*l.* a year would enable those who have charge of it to execute the work; it must take time; it cannot be done offhand, and it would not be necessary to do it all at once.

5757. What is the additional height which you propose to give to the bank?—It would be rather to deepen the bed of the river in most places than to heighten the bank, but the heightening of the bank must be dependent entirely on circumstances.

5758. Have you any other point to which you wish to call the attention of the Commission?—No; that is a matter which I had in my mind, and I thought that perhaps the Commissioners would like to have that view. I have been lately over the upper part of the river with our engineer, Mr. Leach.

5759. When you speak of storage do you refer to the additional sectional area of the river created by raising the bank and dredging the bed, or do you refer to any special reservoirs that might be formed on the adjoining land?—To the deepening of the river and also to the reservoirs which might be made by excavation. In many places the river is very serpentine in its movements from point to point. In a distance as short as from this room to Westminister Abbey you will have four or five turns of the river, and at a very moderate expenditure, by excavation—a straight broad new cut might be made, and that would be the most economical way of increasing the capacity of that part of the river.

5760. Under your present amended powers you are enabled, are you not, to compel parties on the banks of the river or the banks of the streams three miles at right angles from the river to intercept all their sewage and other impurities which have up to this time been cast into the river Thames?—Yes.

5761. What steps have you taken for the purpose of carrying out those powers?—We have power to prevent the introduction into the river of offensive or injurious matter, but where parties under the Health of Towns Act or any other Act of Parliament have permission to pass their sewage by a system of drainage into the river there is a certain course of proceeding pointed out in the Act of Parliament. We have to give them notice and we have to give them time to divert, but in cases where persons wilfully and at once throw filth into the river we take proceedings before a magistrate in the neighbourhood, and if he convicts he may fine them 20*l.*, and we have prosecuted in many instances and obtained convictions; indeed we prosecute in all cases where we find parties wilfully passing impurities into the river.

5762. What steps have you as a board taken in pursuance of the powers granted by Parliament for the prevention of pollution?—The Act requires that we should give notice to the corporations and local authorities that before the expiration of 13 months from date of notice they are to prevent the sewage from passing into the river, and we have given the necessary notices in all cases.

5763. How long have you given those notices?—About four months since.

5764. Have the parties a right to appeal for an extension of time from the 12 months?—Yes; we may give them a time not exceeding three years, and

J. Thorpe, Esq.
27 June 1867.

if they want a further extension of time they must go elsewhere, I think to the Board of Trade.

5765. Your discretionary power is limited to extending the time to three years?—Yes, I think it is three years.

5766. Is that three years from the expiration of your first notice of the 12 months?—No, three years from the date of the first notice.

5767. Then that is an extension of two years beyond the first notice?—Yes, I think so.

6768. Have you served notice upon all the local authorities on the river?—Yes, from Oxford downwards.

5769–5773. To the extent of your jurisdiction?—Yes.

5774. Do you know the paper mills above Cookham in Berkshire which are pouring their filth into the Thames?—No; I do not quite know what you mean by filth.

5775. I am speaking of the result of their manufacturing?—They may be passing something into the Thames, but I am not aware that they are passing into it anything which would be considered damaging to the river, and which we ought to prevent. There is some refuse from paper mills which is not objectionable.

5776. Are you not aware that this refuse is so fatal as to destroy fish?—No, we have no report of anything passing into the Thames that would poison fish.

5777–5779. Are we to understand, speaking generally, that the Thames Conservancy Board are acting up to the powers given by Parliament for the purpose of preventing that which would pollute the river from being discharged into it?—Yes, we are using every effort to prevent the introduction into the river of anything which would damage or injure the water. You are aware that we took proceedings against the people of Kingston; we did all we could in that case, and in all cases we do everything that we can to prevent the introduction of impurities.

5780. Have you enquired into the condition of the Wandle and other streams, into which the refuse of paper manufactories has been discharged, and if so, has it come to your knowledge that the discharge of that matter into the river has destroyed all the fish? That has not come to my knowledge. I have seen the Wandle within a few days, and the Wandle certainly is in a very bad state, but we have not had power to interfere as I think we should interfere. Until recently we could not cause the diversion of such sewage as had been accustomed to flow into the streams.

5781. I am not speaking of sewage, because there would be very little difference of opinion as to the discharge of sewage, but I am now speaking as regards the Wandle and the discharge of refuse from paper manufactories and mills into it. You are aware that proceedings have from time to time been taken against the discharge of that matter into the river in consequence of its interfering with the stream as a fishing stream?—I am aware that proceedings have been taken, not only with reference to the Wandle but the Medway and other rivers in England, against the paper makers, and when those cases have been heard evidence has been given by some that the fluid or whatever was passed was most injurous, and other witnesses have stated as their opinion that it was entirely harmless, and I have not heard of any stand being made, or any proceedings being taken, or any decision given which has had the effect of putting a stop to the introduction of this matter.

5782. Are you aware that the testimony of some of our first chemists has been directly in opposition to that given by Dr. Letheby with regard to the effect of discharging the refuse of paper manufactories into rivers?—Yes, but there are different characters of refuse as far as I understand from paper mills. Some time since we had a report that from Lloyd's paper mill on the Lea there was a considerable discharge of that which was stated to be most offensive and prejudicial; we had a sample of that taken, and it was analysed and reported upon, and the report was that it certainly discolored the water of the Lea, but that there was nothing in it which could justify the assertion that it was prejudicial.

5783. (*Col. Harness.*) Whose analysis was that?—Dr. Letheby's.

5784. (*Chairman.*) Setting aside the chemical question for a moment and the contradictory character of the evidence, would not it to you as a man of observation appear very obvious that that water which would destroy the life of fish could not be good for the human system?—Certainly.

5785. Is it not desirable, having regard to the fact that the Thames is the source of supply for domestic purposes to this large metropolis of 3,000,000 of inhabitants, that such refuse should be intercepted and not permitted to be discharged into the river?—Certainly; everything that injures the character and quality of the water should be intercepted.

5786. As conservators of the river and as a responsible corporate body having charge of the river, what steps do you propose to take to prevent the discharge of any of that refuse into the river?—I have told you that in the case of corporations and local authorities, the course is pointed out to us in the Act, and that we have done all that the Act requires. In the case of individuals we prosecute them if in our judgment they pass anything noxious or improper into the river. Those are the steps that we take.

5787. You state with regard to the paper manufactories that that which destroys the life of fish must be injurious to the life of man, and ought therefore to be excluded from the water. You have received an opinion from Dr. Letheby, in which opinion he states that although discolouration is the result of discharging that matter into the river, yet that is not injurious. I ask you how you reconcile the opinion which you have given with that of Dr. Letheby?—I have not stated that that which is injurious to fish is not injurious to man. I say that it is.

5788. What steps do you propose to take to prevent that either affecting the fish or affecting the 3,000,000 of population in the metropolis?—I have told you that the Act of Parliament points out the way of proceeding in the case of local authorities and corporate bodies, and if we are convinced and we feel that we can satisfy any magistrate or any other authority that that which passes into the river at a particular spot is objectionable, we shall take such proceedings as the Act of Parliament points out, either by a summary jurisdiction, or we may, if we please, prosecute the parties for a nuisance.

5789. You state generally that that is the policy of your board, but you have taken the opinion of a gentleman whom you represent to be your adviser on chemical questions, and he has given his opinion that no injurious effects would result from the discharge of refuse from the manufacture of paper?—In those instances which I have described, not in all instances, or with regard to all kinds of discharge.

5790. My question, therefore, is, having received that opinion, do you intend to act upon that opinion and permit parties to discharge their filth into the river as heretofore, or are you about to take another opinion, or what course do you propose to take with regard to those manufacturers?—I cannot tell you.

5791. (*Mr. Harrison.*) Do you doubt the efficiency of your powers to prevent this pollution?—Not at all. I think we have full powers now.

5792. Are you aware that this question has been fully gone into and judgment given upon it in Scotland in the case of those paper makers on the Esk below Penycuick, and that they have obliged the companies to go to considerable expense to avoid the pollution which is complained of?—I have been informed that cases have been heard and decisions given, but I am not intimately acquainted with the cases.

5793. You are perhaps not aware also of what has been stated as a fact, that in consequence of the investigations which have since been made they find that

they can convert that refuse to a profitable account?—I think it is very likely, but I do not know it.

5794. With regard to the question of deepening the river by dredging, that would of course involve the necessity of lowering the sills of all your locks, would it not?—There are but four locks in the upper part of the Thames from Oxford to Lechlade and all the way to Cricklade.

5795. (*Chairman.*) And those are all to pieces, are they not, like the other locks?—They are all in a very poor state.

5796. (*Mr. Harrison.*) Have you no power at present under your Act of rating the riparian proprietors to your funds?—We have not.

5797. Do you think if you could show so good a case as that which you have stated now, you would have much difficulty in getting Parliament to grant you that power?—I think not; the landowners would be very glad themselves to promote any measures which would have the effect of relieving them of floods.

5798. In the Act which you obtained last session the committee refused you those powers, did they not?—I am not aware that they did. I am not aware that the powers were asked for. That Bill was promoted by the Board of Trade, it was not promoted by the Conservators, and I am not aware that the Board of Trade asked for any such powers.

5799. Your funds are not sufficient at present, I presume, to carry out such a work?—No, we have two funds for Conservancy purposes, the one applicable to the river from Staines to the sea, and the other to the upper Thames. The funds raised for one purpose are not applicable to the other; we have to keep separate accounts.

5800. At present you have no funds at your command to enable you to carry out this deepening of the river above Oxford?—No, we have not the funds to enable us to carry out that which I have suggested.

5801. But independently of that, to the extent of an additional 50,000,000 gallons a day, which, by agreement, the water companies have power to take, you see no difficulty whatever as regards the Thames navigation?—None.

5802. (*Chairman.*) Assuming 30,000 acres to be subject to the periodical flooding which you state, if freed from that flooding it would be increased in value something like 25*s.* per acre; this increased value, say of 1*l.* per acre, would give you capitalized 600,000*l.*?—Yes, but suppose we take it in the other way; what rate per annum would they be willing to pay to the board? We could not spend all the money at once.

5803. If, for example, the proprietors could be convinced that the value of 30,000 acres would be increased by 20*s.* per acre if the several owners were prepared to contribute a rate which would in a given number of years pay off the required sum; giving them some moiety of the saving, the whole cost might be defrayed out of the improvement of the land in question, without the Thames Conservancy or the water companies contributing one shilling?—Yes, but we must look at it fairly. Who are likely to be benefited by those works? The landowners only? Certainly not. The landowners, the water companies, and the navigation. Then, I say, let all fairly contribute. If it is ascertained that 30,000 acres is a fair admeasurement, then an annual tax of 2*s.* would give certainly 3,000*l.* a year, and that for as long a time as such contribution might be necessary, and that would be a very handsome contribution. Then the water companies, who would be greatly benefited, must contribute a fair proportion, and the navigation, I think, probably would increase, so that the receipts from that source would be augmented. The course which I have suggested seems to me to be by far the most economical way of improving and increasing the water supply from the Thames.

5804. You have a contract, have you not, with the existing water companies, that on payment of the sum of 5,000*l.* or 6,000*l.* a year, you, in consideration of that payment, enter into a covenant with the companies to do certain things; to intercept sewage, and to purify the river as a source of supply?—We entered into no such agreement.

5805. Under the recent Act, the water companies contribute 5,000*l.* or 6,000*l.* a year?—Yes.

5806. They contribute that 5,000*l.* or 6,000*l.* a year not for the water which they are now taking, in order that you should, as conservators of the Thames, not up to Staines, as before, but beyond Oxford, as now, intercept, or cause to be intercepted, all filth which now finds its way into the river; in point of fact, to protect the purity of the river in consideration of their paying you that sum?—Yes.

5807. Have you any impurities pointed out in that agreement beyond the sewage of the several towns and villages, and, if so, is one element of impurity that of material discharged from the manufacture of paper?—The water companies agree to contribute 5,000*l.* a year, and it is the duty of the conservators to prevent, as I have stated to you, the introduction of sewage into the river in the mode stated in the Act, and it is the duty of the conservators to scavenge the river, that is to say, to withdraw from the surface or body of the water anything likely to affect its quality. That we do daily.

5808. I am now speaking, not of the water as you find it in the Thames, but as to the contract between your body and the several water companies; what are you to give in return for the 5,000*l.* or the 6,000*l.*?—There is no contract; it is under clauses in the Act that they are to contribute so much.

5809. That is in consideration, is it not, of their contribution; you would not get the water companies of London to contribute 5,000*l.* or 6,000*l.* each, except for a certain consideration?—If you look at the Act you will see what it says.

5810. (*Mr. Harrison.*) In addition to what you have stated, you are also to keep it clear of weeds and such things, are you not?—Yes, to keep the channel clear and to prevent the introduction of sewage, and to scavenge the river, or to do any other work which may be rendered necessary.

5811. (*Chairman.*) You are not able to say whether in enumerating the several matters which are to be intercepted from flowing into the river, the refuse from the paper manufactories is one?—Anything that is injurious. Provided anything which passes from a paper mill is injurious, then it would be our duty to stop its introduction into the river, but I think there is some time given for that, that certain notice is required. There is a special provision with regard to paper mills in the Act.

5812. (*Mr. Prestwich.*) Would your suggestion do away with the necessity of reservoirs above Oxford?—It would almost convert the river into a long reservoir, and for a time it would obviate the necessity of making additional reservoirs; indeed, as far as I know, after having thought of it as well as I have been able, I think it would obviate the necessity of forming reservoirs altogether.

5813. It has been suggested to us that the flood water should be stored in reservoirs, and by that means the flow of the river should be regulated, but you would propose to regulate the flow by deepening and embanking the river?—By deepening and widening, by excavation and by additional water space along the river.

5814. And you think that that would be sufficient?—I think so, or, at all events, for a considerable time; and it would render the construction of other very large reservoirs unnecessary.

The witness withdrew.

T. Macneill, Esq.

27 June 1867.

TELFORD MACNEILL, Esq., examined.

5815. (*Chairman.*) You are a civil engineer, are you not?—I am.

5816. Have you turned your attention to the question of an improved water supply to the metropolis?—I have.

5817. Have you some general scheme by which you propose to take water from Bagshot Heath and the adjoining ground?—Yes, that is so.

5818. Will you describe to the Commission the general features of your plan?—The Bagshot Heath district, which is coloured yellow on the map before the Commission, is a sandy district, where there is very little water at present. It was at one time proposed to bring water, even the small quantity which is in that district, to London, and the whole of the evidence which was given then showed that the water was very good, and that the sands had great power of purifying the water. It occurred to me that as scarcity was the only drawback to that supply, and the water of the Thames flowed so near to it, it would be quite easy to bring the Thames on to that district.

5819. When you speak of purification by means of sand, do you mean that it acted as a filter in abstracting that which was held in mechanical suspension?—Yes, and a great deal more.

5820. How does it deal with that which is held in solution?—It is a process of natural filtration which is not merely sifting the water—it is irrigation and oxydation, with several other things which takes place with the water when it is spread over a large district and allowed to get at the air and at the roots of plants.

5821. That applies to all rain water, but you are now speaking of a filtering bed, that filtering bed being the sand; and that, you say, has a tendency to purify the water?—This is not altogether a bed of sand, there is sand underneath, but it is covered with a bed of peat and decayed heather, which acts as charcoal to a very great extent in purifying the water.

5822. How do you call decomposed vegetable matter, charcoal?—I am no chemist myself, but in the pamphlet which I have sent in to the Commission I have taken the liberty of making some quotations from two eminent chemists, Dr. Angus Smith and Professor Clark. The former, in speaking of this, says, "It is an old remark that humus acts as a char-
" coal filter, although its action here, except as a
" strainer, is difficult to understand, the soil does seem
" to be formed of a mixed charcoal and sand filter,
" which does its work very effectively all over the
" district," and the result of what they say is this, and without exception all chemists who have examined that district, as far as I can gather from them, state that it has very great power of purifying waters, no matter what amount of impurities they may contain.

5823. Do you mean the peat or the sand?—I mean both together, and besides that the filter is of such enormous size that 12 months water remains in the sand, so that it is actually undergoing this process for 12 months.

5824. When you speak of purification do you apply that term to rain water which falls upon the earth, because that is pure in itself?—No. I apply that term altogether to water which is conduced to the Bagshot Sands which I propose to conduct by this process. I have been speaking to Dr. Frankland about this subject from the first time that I had started this proposition, and he offered to investigate it chemically, but unfortunately I have not been able to put him in a position to do it as yet.

5825. Will you proceed to describe your scheme as an engineering scheme?—I propose to give a supply of 200,000,000 gallons daily in the following way. At Teddington weir, where the Thames flows over, I propose to intercept the water and bring it back, as is shown upon the plan before the Commission, in an open cut to near Weybridge, which is 8 miles, where it meets the Basingstoke canal.

5826. Do you propose to take it back simply for the purpose of filtration?—Simply for the purpose of thorough purification and for storing.

5827. Do you go back by gravitation?—Yes, the water gravitates in the open channels, but it is artificially raised into them.

5828. What is the height at Teddington as compared with the site coloured yellow on the plan?—The water at Teddington is 14 feet above Ordnance datum.

5829. I understand you to say that you return the water from Teddington back to the Bagshot Sands for the purpose of filtration, and to enable you to do so you must have four lifts?—Yes, there must be four lifts. The height of the Bagshot Sands varies from 380 feet to 200 feet.

5830. Do you gain any other advantage than simply that of filtration by returning the water from Teddington to Bagshot?—I think so. The water is not only filtered, but it is turned into what may be called spring water, and it never sees daylight from the time it is poured over the sand till it is delivered into London, and the sands will contain 12 months supply.

5831–2. At what depth in the sand do you tap that storing power?—The conduits shown by the red lines on the outside of the yellow district are sunk 30 feet below the surface, and that is about 10 feet below the natural saturated line. The centre conduit will average about 130 feet in depth. I have brought with me a model by which my plan will be much more easily explained. The Thames water is to be brought up by the Basingstoke Canal which passes through the Bagshot Sands; it arrives there at a 200-feet level, and it is sent round in a distributing conduit in this way (*describing the same upon the model*) in order to distribute it into the sands.

5833. This I understand is your channel out of which the water flows into the sands?—Yes.

5834. Is it open cutting?—Yes.

5835. It is an open cutting of course put in with puddling?—There need be very little puddling, if any, the object being to allow the district to absorb the water.

5836. And the water running or standing in this channel will sink rapidly into the sands?—Yes; there are branches from this channel which irrigate the district.

5837. What would be the absorbing power of the sand?—That I have a most excellent proof of. There are natural holes in this district which fill up with water when there is heavy rain, as was the case last winter, but before it had time to disappear the frost came upon it and froze the surface. I went there a few days after that and all the water had disappeared; a skim of ice remained upon the top, but all the water had gone, and that gave me a calculation of the quantity of water that would disappear in a certain number of days, and that was at least equal to an inch in depth over the whole area, which is nearly 14,000 acres; that is a proof of the absorbing power of the sand.

5838. When you say that the absorbing power is equal to an inch over an area of 14,000 acres, does that apply to the whole ridge?—Yes.

5839. How many gallons is that?—That would be equal to 400,000,000 gallons a day. I should mention that that was in an unfavourable place where there was a little more clay and turf carried down from the slopes than was met with in other places.

5840. What depth are those holes on the model?—Not more than three feet.

5841. But are there not points at which the water is discharging from those hills?—Yes, several places.

5842. The capacity of that absorbing power being exhausted the water must naturally flow out in all directions?—The water would flow out in all directions if it is supplied with water. There are small springs, but there is very little visible water indeed in this system of hills.

5843. And you propose to go 30 feet lower?—Yes.

5844. One system is to bring the water and to discharge it into this sand which has that absorbing power?—Yes.

5845. Another is to tap the sands at a level of 30 feet below the surface in order to carry the water back to the metropolis?—Yes.

5846. What does that 30 feet below the surface mean?—It means the outside conduit (*pointing out the same upon the model*).

5847. What depth would that 30 feet be from the ridge—the backbone of this model?—More than 200 feet, but there are other distributing conduits and catchments besides the outside one. The lowest distributed water as I have said before is at 200-feet level, and it encircles the whole of the Bagshot district. I propose only one set of pumps for the whole district. Then there is another level of distribution at 380 feet, and from all these there are small streams to the right and to the left. By that means of distribution the sands will be able to absorb more than double the water that I propose to bring to them.

5848. Where do you propose to tap it?—I propose a conduit to London to run along the Hogsback to Norwood, and from that point it is 36 miles to where it crosses the London and South-western Railway near Foxhill. When once the water gets to that point it runs by gravity to Norwood, where it is on a level of 210 feet above Ordnance datum. The red line represents the lowest catchment on the east side, and the other lines represent the lowest catchment on the west side; they are all intended to be sunk at least 10 feet below the present saturated line or existing water level, and they completely encircle that space, so that there is no possibility of the water escaping.

5849. (*Mr. Harrison.*) Do you get down to the London clay there?—No, the London clay is underneath, and it holds up the water at present which depth is measured by the wells of the district.

5850. How far is the London clay below where you are?—I am not sure, it is a considerable distance below, but we have an impervious stratum before we come to that, and upon which I rely to prevent escape. It is pure sand, but it is saturated with water. The water that we put upon it cannot penetrate through the saturated sand, and it can only find its way out in a lateral direction. These conduits being sunk at a greater depth than that must intercept the water. There is a catchment applicable to each main drain, and from those catchments we run up drains at right angles to the catchments. The character of those drains is explained by this section (*producing a section, and explaining it to the Commission*). There are a certain number of holes all along the crown of the arch of the drains in the line of that vertical bed of stone. These stones allow the water from a large area to trickle into the drains. The conduit has various falls, some 10 feet per mile, and others less. The minor drains are proposed to be 20 feet deep, and there are 100 miles of them. By these means the water is absorbed in both directions, having lain in the sand upwards of 12 months, gradually finding its way into the drains. I have tried some experiments which prove that there is a slight current in the water when the saturated plain is inclined 1 in 80. The method of distribution is shown on this plan (*producing a plan, and explaining the same to the Commission*).

5851. Having explained the process of taking the water from Teddington to Bagshot Heath, and distributing it on the sand, and your mode of tapping that basin for the purpose of conveying the water to the metropolis, will you state by what sized culvert you propose to carry the water?—The London culvert for 36 miles I propose to make of 14 feet diameter.

5852. That is to be covered all the way, is it not?—Yes, that is to be covered all the way. I at first proposed that it should be 18 feet, but 14 feet will give 200,000,000 gallons a day, and if you ever require more, there can be another conduit of the same size made alongside of it. There are only three syphons in the whole of that conduit.

5853. What is the dip?—About 130 feet. I have estimated the cost of viaducts in those three instances, and I am much inclined to say that viaducts ought to be constructed instead of syphons; the conduit would then have a uniform fall the entire way of one foot per mile up to Norwood.

5854. And at Norwood you propose to have a reservoir?—Yes, a service reservoir partly covered and partly open.

5855. Of what area?—80 acres; the covered part to hold half a day's supply, and the uncovered part $2\frac{1}{2}$ days' supply.

5856. What proportion of the reservoir would be covered?—The whole is three days supply, so that it would be one-sixth covered. The object of doing that is that the water may always run through the small reservoir, and that will keep it cool and pure, and in case of emergency the water that remains in the uncovered part might be used.

5857. What height are you there above high water?—212 feet above Ordnance level.

5858. Where do you propose to take it from Norwood?—To Hampstead.

5859. What is the difference of level between Norwood and Hampstead?—Hampstead is a few feet lower than Norwood.

5860. Is Norwood sufficiently high to give you the necessary head to carry it to Hampstead?—Yes.

5861. Will you describe to the Commission the means which you propose to adopt to carry it from the one point to the other?—When I got the water to Norwood I saw there was great difficulty in distributing it. If you bring water to one end of a large place like London, and have to send such a volume of water as is proposed all through London, a great number of new pipes and mains would be necessary, and a great loss of head would be the result. I propose that there should be one large main to run right through London, 10 feet in diameter, made of wrought-iron, or an equivalent in two mains.

5862. You must have a considerable dip?—It runs down to the Thames and up to that part of Hampstead. There may be a difficulty near the Thames, but the rest is very simple, and the object to be attained is so important that any difficulty that may arise may be met.

5863. It must be an immense syphon?—Yes.

5864. What is your head of water at Norwood?—At Norwood it would be 212 feet, and at Hampstead we should take off 12 feet. The object of that is this: by putting down a syphon, and vertical pipes to connect with existing mains, they are at once doubled in power, because you send a flow of water in both directions.

5865. At what point do you cross the Thames?—Near Chelsea.

5866. Would you take your main pipe over or would you tunnel under the Thames?—I am disposed to say that it ought to pass over the Thames.

5867. On one of the bridges?—No, by a new bridge.

5868. Would you have a series of pipes?—Yes, I think it ought to be a double pipe; the pipes to make in themselves the bridge crossing the Thames.

5869. What is your estimate for your structural works, commencing at Teddington to Bagshot, with your distributing mains and pipes, and your tunnel from Bagshot to Norwood; and will you give the estimate separately if you can from Norwood to Hampstead?—I have estimated the works very full; and for conveying the water from Teddington as I have described, irrigating the sands, and collecting the water, and the construction of the conduit to Norwood, including the reservoir there, the estimate is 5,000,000*l.*

5870. And what is your estimate for the works from Norwood to Hampstead?—Over 1,000,000*l.*

5871. Is that including the reservoir at Hampstead?—Yes, but that does not of necessity form part

T. Macneill, Esq.

27 June 1867.

of the scheme. The water may be distributed from that reservoir as from any other.

5872. And what is the total estimate for all your works up to the distributing mains in the metropolis?—I do not estimate anything further than the bringing of the water to the reservoir at Norwood. I do not propose to go into details for anything further than that.

5873. How do you propose to raise the funds?—That I have not considered.

5874. You have no idea as to any special mode of raising a fund of 6,500,000*l.*?—No, I have not. I consider that London wants a good supply of water, and that it would not be easy to get it from any other quarter than the Thames or at a less cost.

5875. Has it occurred to you whether the advantages are equal to the outlay involved in taking the water back from Teddington to Bagshot, with all the costly arrangements for distributing the water on the sand in order that it might be absorbed, and then taking it back again to London in an expensive tunnel, as compared with tapping the Thames at a lower point, and forming filter beds for the purpose of purifying the water?—I have fully considered that.

5876. What is the contrast?—The contrast is very much in favour of what I propose, as far as my judgment goes.

5877. Do you mean as to cost?—No. Supposing the water were raised from the weir at Teddington now, and it were fit to be used in London, and it were raised and pumped up direct to the reservoir at Norwood, it would require practically the same amount of pumping power to do that as to bring it the whole way to the Bagshot Sands and back again to London. That seems a contradiction, but I will explain why it is not so. There is a large quantity of water that comes down at Guildford which is added to the Thames water, and at the point named, Horsell it joins the Thames water in the Basingstoke Canal at the 68-feet lift.

5878. Do you mean to say that your four lifts are not more than would be necessary to raise the water to that point?—One-tenth more, simply because you must use iron pipes to raise the water direct at Teddington, and an iron pipe requires more fall per mile than a large brick culvert, so that what you gain in the short distance you lose by the greater fall.

5879. Surely if you cut off the structural expense of this work from Teddington to Bagshot, and get rid of four distinct lifts and all the network of pipes and catch drains, or whatever you call them, in the sands, as well as the return to Norwood, the cost of carrying the water from Teddington to Norwood must be very much less than the plan which you suggest?—No doubt, but I say that the engine power required and the annual expense of pumping is not much greater.

5880. What engine power have you for those four lifts?—I have divided the engine power into three. There is first the bringing of the water from the Thames to the sands, which requires 7,000 horse power, to which I add one half, which makes 10,500 horse power.

5881. (*Mr. Harrison.*) That is the accumulated power of the different engines for the different lifts?—Yes. There is first the Bushy Park lift of 30 feet, there is another at Weybridge of 85 feet, there is another lift further on in the canal of 68 feet, and that brings the water on to the sands. The united power of that is 7,000 horses, to which I add one half, which makes it 10,500.

5882. (*Chairman.*) What power would be necessary to lift the same quantity of water from Teddington to Norwood?—Before answering that I had better say that more engine power is required, because that only brings the water to the sands, and to distribute it requires an extra power of 6,000 horse power, one-half, as before, being added for duplicate power.

5883. Then that would be 16,500 horse power?—Yes; and in order to lift the filtered water from the lower conduit it takes 3,500, or in all 20,000 horse power; that is including the duplicate power.

5884. Returning to my former question, having regard to the same quantity of water raised from the level at Teddington to the height of your reservoir at Norwood, what power would be necessary to lift it?—The theoretical power required by the plan which I propose is 13,378 horse power. The theoretical power to raise that water from Teddington to the reservoir at Norwood is 12,000 horse power, and that is, as before stated, a difference of one-tenth.

5885. There is a difference of one-tenth in the power and all the cost of the structural works?—Yes.

5886. What is the advantage, therefore, of your system of filtration over the system of filtration which is now adopted by the companies at Hampton?—I cannot speak as a chemist, and must refer to the many quotations in the pamphlet describing the advantages. I have consulted Dr. Frankland, and he has authorized me to say that he shall be happy to conduct experiments, but they have not been conducted at present.

5887. But, speaking as an engineer, you invite us to take the water from Teddington to the Bagshot sands for the purpose of filtering, and then to bring it in an expensive channel up to Norwood. I ask you why you should take the water back so many miles from Teddington to Bagshot, 16 miles, and returning it necessarily 16 miles, making 32 miles of waste?—My answer to that is that if you take the water direct from Teddington I conceive that it is utterly unfit for the use of a town, whereas by the process I propose it will be delivered at a uniform temperature throughout the year and perfectly purified.

5888. Supposing it is subjected to sand filtration, which is all that your water is subjected to, with the exception of the mixture of peat which you call charcoal, what is the difference between the present process and the one that you propose?—There is in the first place 5,000 times the extent of filtration of the water by my process above ordinary filtration. The water is subject to the improvement which takes place by the growing of plants, which very much improves the water. The great fault of the water at present coming into London is its containing nitrates and nitrites, which, as I understand Dr. Frankland says, can be removed by the process which I propose it to go through. In fact the water, after undergoing that process, will not contain the trace of the sewage which it has now, and the water will always be of a uniform temperature; but to show the difference between the process now recommended and that of ordinary filtration I had better read some remarks of Dr. A. Smith on this point:—

"The power of sand to purify water is really very great. I tried a few experiments upon it, which I may as well mention. A strong alkaline solution of peat was made and passed through sand; the water came through clear, retaining only a taste of the earthy portion of the sand.

"It seem probable that there is here an action independent of the ordinary chemical affinities; but as far as the purifying of the water is concerned it is enough to know that it is a fact.

"It would not be correct to say that sand is the most powerful filterer in proportion to its bulk, it is too coarse generally to act except when there are large quantities, and other substances purify the water using much smaller quantities. It is however so general, and it is used in nature for purifying water so frequently, that it deserves most attention. The sand requires to be of considerable thickness, at least so that the water does not run too fast off; but at the same time nearly all the impurities removed will be found on the surface of the filter.

"Percolation through a porous stratum is capable, in fact, of removing any amount of organic impurities from water, as the universal admiration of spring water sufficiently shows; and this removal of the organic matter, which is an objection to surface water, has generally been considered a sufficient compensation for the inorganic matter and hardness which it has acquired in the process by going down to great depths and remaining a long time. It is true, that to remove the last traces of organic matter seems to require that the percolation be continued a considerable length or space.

"It happens here, as in other cases, that the purity is according to the extent of the process of purification." * *

"From the manner in which I find this paper has been written it will be better that I should give a short abstract of what I believe true on the subject.

"The Surrey district is composed of sand and shingle, with a thin covering of heath.

"The water from it is soft, varying from one degree to six degrees of hardness.

"The nature of the surface renders it exceedingly fitted for natural filtering, or purification by drainage through the substratum.

"This is the mode in which the purest waters are obtained, and by which the purest waters are got from peaty districts.

"This mode of slow filtering removes all organic matter from solution, so that the organic matter on the surface is a matter of less importance, as it is remedied by drainage.

"This is the method by which spring water is prepared, and by which it is aërated, or supplied with carbonic acid and oxygen.

"This water might be supplied to towns without filtering, unless by some unforseen circumstances it might be somewhat diminished in brilliancy during its flow.

"This has an advantage over the river water in softness and in absence of organic matter, which qualities must be produced by artificial means when river water is used.

"The comparison in expense and practicability must be a matter for further investigation.

"This mode of filtering removes iron in the state in which it is found in parts of the district. As far as surface is concerned, the district in Surrey is peculiarly fitted for this mode of purifying water.

"Water so purified could become nowhere putrid from want of the material which putrefies. Peaty matter itself does not putrefy: even if it were not removed there would be very little organizable matter, much less than in the neighbouring rivers.

"Reservoirs with water thoroughly purified would not become filled with vegetation in the light or in the dark. To prevent water from putrefying, pre-supposes putrid matter. Water should not be supplied with such matter in it.

"As little rain as possible ought to fall into reservoirs; unless, perhaps, many miles from towns, the impurity of the rain, even outside of towns, being very great.

"It may be objected that water so pure as this cannot be got; and this brings us to another reason, the reason which seems to me most in favour of covered reservoirs, arising from the impurity of rain got from the neighbourhood of towns. This impurity must be very great near London, and probably several miles from London. I have just been collecting water from the fields a mile from Manchester, and about two miles from any large chimney; it is very impure, and of a bad taste; it could not be used as a supply for a town without careful filtration. I reserve the description for another occasion. It would be an important thing to know at what distance from London it would be safe to leave reservoirs uncovered, and whether at any distance whatever a large amount of rainfall would be an injury. It would probably be refining too much to speak of any injury to distant reservoirs from rain; but as to supply reservoirs in the neighbourhood of the town it would not at all be over refining, as the amount of impurity is very decided. If the water could be got so pure as not to require filtering, then the reservoirs at the town would not be wanted, or at least diminished to a very small size. If it should be found that filtering cannot be dispensed with, the removal of filters far into the country will, I believe, be an improvement, as in that case they will get the water in a clearer state, and have less duty imposed upon them." * * * *

"Water purifies itself from organic matter in various ways; by forming nitrates, as in sewers, and in the neighbourhood of cesspools and churchyards, under streets, in manured grounds, and other repositories of organic matter.

"This may be done in a laboratory on a small scale, where animal matter by means of a sand filter, may be converted into nitric acid.

"In the larger operations of nature the carbon also is oxidized.

"Sulphurated hydrogen is also oxidized on a small scale by a filter, being converted into sulphuric acid.

"A filter, therefore, as an oxidizing agent, acts in proportion to its cubic contents.

"Water falling on the surface of the ground gets rapidly saturated with organic matter; but in passing through the soil gets filtered, and the matter oxidized, making the porous soil and the air the great agents of purification in a country; whilst drainage will act in removing organic impurity as well as mere water." * * * *

"This growing of plants and animals is, therefore, a good mode of cleansing water, when space and time are abundant, as in the larger operations of nature, but unfitted for waterworks where neither are very ample." * * * "The hard water will, of course, be better able to feed land with its soluble manures; or, if we choose to express it otherwise, the plants will more readily feed, finding the food more soluble."

And he gives the following description of the filtering district proposed for purifying the Thames water:—

"I shall describe the state of the heath as far as relates to natural means for purifying the water. The district is covered by sand, or by shingle if it may be so called. This sand is a reddish brown, and in some places has a considerable depth. On the surface is heath. The upper forming the soil of the heath is composed of peaty matter and sand; the peaty matter gives the blackness. When the peat is washed away the sand is found to be a pure white. In many places where the plants have been removed and the rain has begun to wash away the peat, the mixture of the two gives a peculiar colour to the ground, a grey with a tinge of purple in the distance. Sometimes the peat is found entirely removed, and then the sand or flints are found perfectly white, shining on the surface. The reddish sand lies immediately under it, and this effect has been produced merely by taking off a few inches, a mere scraping from the surface. The sand of the surface mixed with the peat is evidently washed white by the acid of the peat, and it is remarkable how decided this line of white and red is over the district. The soil is such a good filter that none of the acid goes much below the surface, so that there is no white sand to be found above a few inches deep generally, as far as I saw, about eight inches, although there were cases where it was not so deep, and also cases where it was two feet deep. As the upper sand must retain matter in solution to cause this whiteness, so the under sand not being acted on, it must be penetrated by water having no such matter in solution. It follows that the peaty matter must get filtered out before it passes from the upper layer to the under layer. It is then an interesting fact that at the junction there is a blackness, a black line in fact running along under the surface having white sand above and red sand below; it is in fact the line of filtration. It is an old remark that humus acts as a charcoal filter, although its action here, except as a strainer, is difficult to understand; the soil does seem to be formed of a mixed charcoal and sand filter, which does its work very effectively all over the district.

"The sand above is found to be saturated with water, while the lower sand, not more than a couple of inches from it, is only damp, showing that the water passes through very slowly, and so has time to undergo the process of filtration, which is not a mere straining through a sieve, but an act of purification. The black line which is an accumulation of carbonaceous matter is a considerable hindrance to the passage of the water. This will perhaps account for the great part of the water in the streams, at least in the Bagshot district, being surface water, as the water will have a greater facility for moving forward above the line of filtration. If the water in the ponds is in many cases water which has passed through the soil, and been thrown out by impervious formations, it will account for the greater freedom from a peaty taste and also for a greater hardness than is found in the streams.

"It might be asked if this filtering removes the iron, and the answer is already to be found in the wells and springs; if the iron is in combination, as I believe it is in most cases, with peaty matter, they will be removed together. At any rate they are both removed. Professor Way has removed many inorganic salts by clay and soil, and shewn that they are absorbed by clay especially in great abundance.

"But to obtain these results the water must be allowed to pass through the upper stratum; thus the filter, instead of occupying only a few acres, straining the water from its grosser impurities, will be a thorough natural purifier, where the water will be elaborately cleansed by the ordinary natural processes which form the best spring water. The water in that case will not be allowed to stand so long on the surface and become impure in contact with the surface; this will prevent evaporation such as occurs in some parts of the district where there is a stagnant water, it will also prevent the necessity of extensive artificial filtration, which the use of this natural filter, will to a great extent, if not entirely, supersede. * * * *

"Water taken above the point of filtration, that is not having passed below this stratum, contains much organic matter; but below this line it is true drainage water, and is purified like water from a shallow spring. Leaving the cause for examination elsewhere, these facts lead to the conclusion that the power of filtration to remove colouring organic matter in solution is really enormous: but it must have time, as the action is not a mere straining through a

T. Macneill, Esq.

27 June 1867.

sieve; the artificial filter is for this reason generally too small for the full effect obtained by the natural mode of filtration, where time is given for a complete act of purification.

* * * And in answer to the question, "Even if little or nothing were done either on the surface or with the mode of collection, we are to understand, then, that the supplies drainable from the greater portion of these Surrey sandy districts would be on an equality with the soft water supplies of the northern towns you know of, as at present collected and distributed to them?" he answers: "Yes, certainly."

5889. (*Mr. Harrison.*) Do you expect that the filtration will reduce the hard chalk water to soft water?—Yes.

5890. Can you speak to that from positive experiments?—No; but I may say this, that the water of the Thames added to the water of Guildford in their relative proportions reduces the mean hardness of the water, before spreading over the sands, to 8 degrees from 13 degrees, which may be considered as the average of London water.

5891. (*Col. Harness.*) The river Wey is very nearly pure, is it not?—The water of the Wey is very soft.

5892. (*Mr. Prestwich.*) The mass of sand through which you would propose to filter the water forms, does it not, the upper Bagshot Sands?—The upper and the lower.

5893. And they are from 100 to 150 feet thick?—The upper sands would be about an average of 130 feet.

5894. And that is covered over in a part of those hills by gravel and peat?—Yes.

5895. Therefore, you believe that there would be a tendency to remove all organic impurities in the water passing through so large a mass of sand, covered by peat and gravel?—Yes.

5896. From your own knowledge, have you any reason to suppose that the carbonate of lime and the nitrates would be removed by such a process?—No, not from my own knowledge; and it is of no use referring more than I have done to chemists' opinions, which I have quoted in the pamphlet that I have handed in, because all that I could say is second-hand; but judging from people who have examined the question, I should expect a very great reduction in the hardness of the water, besides the total removal of all the impurities of the Thames water.

5897. But the instances that you give in this pamphlet do not apply exactly to your own case?—No, nor do I think I could find any instances. The way to find it is, as I have suggested, to get Dr. Frankland to examine it. I have spoken to him two or three times about it, and I can say, from what he has told me, that I have a still better opinion of the scheme than I had before I spoke to him. An experiment could be tried very easily on the district by passing the Thames water throught it with a proper proportion of Guildford water. The canal comes from the Thames and passes through the district, and it would be very easy to prepare a small district in the way I have proposed, and to pour over it the Thames water brought by a barge; it would not require a very large district to determine the question.

5898. You have never heard of any instances where passing calcareous water through siliceous sands would result in the removal of calcareous matter?—No, not through pure sand, but I have heard of instances where it has passed through clay and peat.

5899. (*Col. Harness.*) The water you find in the canal is not Thames water, is it?—No, I would bring the water up the canal and prepare an acre of ground, or a larger space if necessary, and throw over it the proper complement of this water, and drain it off afterwards, which would prove the quality, and also, if I am not much mistaken, that there would be no waste.

5900. (*Mr. Prestwich.*) The total area of the Bagshot Sands, which you have taken as a filtering ground, I see on that map are marked, one 25 square miles and the other $22\frac{1}{2}$?—Yes.

5901. The rainfall in that district is about 25 or 26 inches, is it not?—I have estimated the average as two feet; the maximum is 26 inches.

5902. A large proportion of which would pass into the Thames, the gravel being so porous?—Yes, that is so at present. I have assumed over that area of 47 square miles that two thirds of all the rain water will be caught by those conduits, which will be pure rain water.

5903. Apart from your own plan of bringing the water there, have you ever estimated what the rainfall is upon that area of 47 square miles?—Yes. I calculate that the available water due to the rainfall of the 25 square miles would be equal to 16,000,000 gallons per diem.

5904. How much of that is delivered in the streams and watercourses of the district at present?—I cannot say that.

5905. Is not the quantity excessively small? Are not the streams all very small in that district?—The streams are not subject to floods, but I am not aware that the streams do not give out the full proportion of rain water that falls upon the district; some no doubt sink to the saturated line, but on account of the absorbing nature of the district there are no floods on those rivers or streams.

5906. Is not the lower portion of that mass of sand so saturated that it is full of small springs, the water of which is lost by evaporation?—No, I should not say that, as much of it would sink into the lower bed.

5907. For example, take the district between the village of Chobham and the Frimley Ridges, where there is a large extent of heath land; is it not the case that a certain portion of the rainfall which falls upon the Frimley Ridges, which you take as your filtering ground, passes off in a stream which uses that piece of ground?—There is a stream which comes from the Bagshot Sands in that locality.

5908. Have you ever gauged that stream?—No, I have seen many gauges taken of it.

5909. You are probably aware that experiments were made upon all those streams in the year 1852?—Yes, by several engineers.

5910. And the result was, I believe, that the delivery of water from that mass of sands was found to be very limited?—Yes, I think that was so.

5911. If you have walked over the moors in which this stream rises you would have found that the cause of that is that there is no large spring, but the ground itself is excessively marshy and a very large amount of evaporation goes on?—Yes, but I think there is another cause, and one, perhaps, which is even more true than that, namely, that as soon as the water falls into the sand of the lower beds it never comes up again; it gradually goes down an inclined plane till it finds its way out at some place down here on the Thames (*pointing to the model*). My experiments would lead me to think that that was the case.

5912. Is there not a bed of very hard laminated clay in the middle of the Bagshot Sands which holds up the water between Knapp Hill and Frimley?—There is a bed of clay there.

5913. Do you know the Hermitage?—Yes, perfectly well.

5914. Do you know the brick pits there?—Yes.

5915. Does not that bed of clay pass underneath the whole of the district which you take as your filtering ground, this bed of clay being part of the Middle Bagshots?—There is a bed of clay that divides the two sands, the upper and the lower, and that is where all the springs of the upper sands burst out. I expect a large supply from there, and for that reason I have laid out a conduit to encircle it. I have a yellow line on this map (*producing another map*) which shows the line dividing the two sands, the upper and the lower, which line shows a bed of clay of various thickness, said to be from 2 feet to 14 feet. Of course a large quantity of water which is thrown upon the upper sands would come out there, and I have on this plan shown how this water would flow into the main conduit; the rest from the upper sands

would be drained off by the centre tunnel and line of shafts as shown on the model.

5916. The difficulty, as it strikes me, is this, you now see that your collecting ground is very near the outcrop of this bed of clay?—A portion of it is.

5917. Notwithstanding that, the rainfall on the upper sands is very large, and that the bed of clay comes to the surface just at the foot of those hills, and notwithstanding that there is so much water lost oozing through those sands over a large surface not being directed into any one given channel, in the form of springs, the delivery of the water from those upper sands into the streams is excessively small?—Yes. I believe when this water passes over the clay bed much of it sinks into the lower bed of sand.

5917*a*. Therefore it would appear that you would experience a similar difficulty if you were to deliver any large quantity of water into the sands, namely, that you would not be able to collect it, that the water would ooze out on the large surface of moorland where you would find extreme difficulty in collecting it; and you have not made it apparent that you would be able after passing the water into the sands to catch it again?—I quite see what you mean, and I am quite prepared to show how the water could be collected into those channels. It is a question of draining. If you have drains connected with the deep wells, as shown on the model, running through those sands, not shallow drains but deep cuts, with a vertical wall of stones and coarse sand, it will act on both sides as a receptacle for the water to run into the conduits, and I believe, of necessity, the water will have a preference to fall into those artificial streams to seeking another outlet if that outlet has not a greater fall for the water than the one which I propose artificially to give it, because the water and the sand is all one homogeneous mass in the upper sands; so that it is a question of the degree of facility that you can give for the water to get away. If there were clay running through it it might be a different matter, but it is perfectly pure, and all you have to do is to place in that sand a sufficient number of drains and wells which will collect all the water that is thrown upon them, and if any escape at the margin of the clay bed it will be caught lower down.

5918. At present all the rain water which falls on those sands must find its way out, and does find its way out by passing underground a great distance?—That was the lower sands which I mentioned.

5919. With which you have nothing to do?—Yes, I have.

5920. You confine your works to the upper sands, do you not?—No; to the upper and the lower; the greater quantity is the upper.

5921. But you said the lower just now; your plan has nothing to do with the lower sand?—Yes it has, as a large part of the proposed filter is on the lower sands.

5922. You were speaking of the lower sands being saturated with water, but are you acquainted with the well which was sunk at Mr. Waterer's, just at the edge of the middle sands, near Chobham?—No, I have not seen it.

5923. You probably are not aware that they went through the sands and through the London clay, but they could not get any water at all?—I can believe that. As far as my judgment goes it would be impossible to get much water from any one well sunk in these sands with the present limited rainfall, as the incline of 1 in 80 before mentioned from the bottom of the well to the saturated plain would embrace only a small area.

5924. I mentioned that just to show you the difficulty of getting water out of these sands, whether the upper or the lower. Are you acquainted with the well also at the Woking station?—Yes, I know that; and beautiful water there is in one of those wells.

5925. But the quantity is not large?—No.

5926. Are you aware that they are sinking a well on the very top of the Frimley Ridges to the west of Bagshot?—They have gone down very far and have got no water, but I am rather glad that that is the case, because throwing water into the sands here which are now destitute of water would enable such a well to give an abundant supply of water; it shows that there is nothing to prevent the water getting out. It is because of the great purity of the sand that the water runs away.

5927. It would appear to me that it oozes out in such innumerable directions that you could not collect the water after you had thrown it on to the sands, because there is no district round London where there is more difficulty in getting water by wells in those sands than in this very Bagshot and Frimley district?—But there is no instance of sinking wells where you do not come to water by sinking down a certain depth. It is very probably the case that the sand is so dense, that the water trickles through it very slowly indeed. If you make those wells large enough, and make cuts out from them as I propose, you will get water if those cuts are made in a saturated sand, but by merely making a single well down into them, and leaving the water to come in through a small area, of course the water would be very slow indeed in coming in, but if adits are made from those wells I should take it that that would increase the supply very much. I am informed by the contractor who made the railway cutting through these sands that he met with a large volume of water, which I quite believe, for he had here a lengthened cut in the saturated sand.

5928. There is another point to which I wish to direct your attention. Do you know the village of Normandy to the south-east of your district, between the Hogs Back and Box Hill?—Yes, I know the district.

5929. That is where the water of the Middle Bagshot Sand which holds up the water of the mass of sands which you would use as a filter oozes out, and it is a very marshy tract; do you know the character of those waters?—I do not.

5930. Do you know that they are extremely ferruginous?—I do not.

5931. Are you aware that there is a bed of greensand at the base of the upper sand, and at the top of the lower, which contains a great deal of iron pyrites which decomposes and tends to impregnate much of those waters with iron?—I am aware that there is a little iron in the district, but that it was of any extent I was not aware.

5932. And also several of those streams between Chobham and the Frimley Ridge are in the same condition?—Within the district that I encircled there is very little iron.

5933. There is a spring between Chobham and Frimley Ridge which was so ferruginous that it was contemplated some years ago to use it as a chalybeate water, and it is within the area which you have taken?—If there were any small area of that sort which was impure, I can conceive that it would be very easy to cut it out, but that the whole of the upper and the mass of the middle sands are pure I think is undoubted, so Sir Roderick Murchison told me, if I did not misunderstand him; and Dr. Franklin said that a little iron might not be any injury to the water of this district if there was found to be a little, and Dr. Angus Smith says: "It might be asked if this "filtering removes the iron, and the answer is already "to be found in the wells and springs; if the iron is "in combination, as I believe it is in most cases, with "peaty matter, they will be removed together. At "any rate they are both removed."

5934. (*Mr. Harrison.*) You propose to distribute a given quantity of water over an area of altogether 22½ square miles?—Yes.

5935. And your calculation is based upon your collecting the whole of the water again by catch-water drains?—Not all, I allow 10 per cent. for evaporation.

5936. And how much for waste otherwise?—I do not conceive that there will be any waste, I cannot see where there would be any waste.

5937. You base that upon the assumption as you

T. Macneill, Esq.

27 June 1867.

state it as a fact that your lower catch-water drains would all be in sand, which is now so entirely saturated and held up by the beds of clay which surround it that there can be no waste below the level at which your lowest catch-water drain is to be placed?—No, there cannot; whatever waste takes place now I would let take place, I would not interfere with the existing waste, but that water which I throw within those catchments I conceive will be all got again.

5938. Still the whole scheme depends upon that?—Yes.

5939. In the next place, one object which I presume you have in view is that by this complete filtration you would convert the hard chalk water into soft?—I should hope so.

5940. But you only hope so?—I have no proof of it, except so far as the mixing of the rain water and the Guildford water with the Thames water reduces it from 13 to 8 degrees.

5941. But that does not follow when you come to mix merely the rainfall of a small area with the enormous quantity of water which you have to pump there?—But the quantity coming in from Guildford is considerable. Then there is the canal, which drains a large district, and I propose to utilize that water, and taking the hardness of these waters and their relative quantities; the mean before filtering is about eight degrees of hardness by Dr. Clark's scale.

5942. (*Chairman.*) You stated, did you not, in answer to a question that was put to you by Mr. Prestwich, that the general reason why so small a quantity was finding its way from that area through the river and the channels from the sand was that it was secretly finding its way to the Thames in some other quarter?—Yes, that is what I believe.

5943. What guarantee have you that of the water which you bring from Teddington and pour on to those sands a large proportion may not find its way secretly out and not be caught in the channels which you propose to collect them in?—I base my proposition upon this fact, that those conduits will be sunk below the present escape of the water, that is to say, 10 or 12 feet, or more if necessary, below the levels at which those waters are now oozing.

5944. Then you have detected the source of escape?—No, it is not an escape, it is oozing; there is no one place that I am aware of where the water runs as an escape, but there is a tendency in the water to fall from a high level to a low level, and I have proved that 1 in 80 gives a visible motion downwards.

5945. (*Col. Harness.*) Then do you draw a line of 1 in 80 to the nearest point and intersect that line?—Not quite that. I would sink wells along the line of catchment in the first instance, and by that means the water in the wells gives the saturated line, and below that line I would sink the encircling conduit.

5946. (*Mr. Prestwich.*) In the section which you draw on your plan you say, "line of saturation held up by the London clay;" are you aware that that is a mistake?—No, that line indicates the saturated line when the conduits are at work, or more correctly speaking, is the bottom of the filter.

5947. You admitted just now when I pointed it out to you that in the Middle Bagshot Sands there would be sand mixed with a considerable amount of clay which holds up the water, and it is those middle beds is it not, which hold up the water in your filtering district?—That is as far as the upper sands are concerned, but the filtering extends beyond that very considerably; the lower catchments are not in that.

5948. According to your plan, is it not limited to the upper sands?—No.

5949. Just confining yourself to the upper sand, that is the largest proportion, is it not?—It is about half I think.

5950. I want to prove that it is impossible for any water to pass underground from that district and to escape unseen by the Thames, because the rain water in those upper sands are held up by those middle beds?—Yes, that is so, and entirely agrees with my proposition and views, and I regret I did not see the drift of your question before, but I confounded the middle beds of clay with the lower beds, hence my want of a clear explanation.

5951. Don't those middle beds crop out immediately to the east of all your filtering district, by Chobham?—The lower catchment is on the east of the outcrop at Chobham.

5952. As they are impervious, is not all the rain water that now passes into those upper sands held up and delivered at that point?—Precisely so; so far as the upper sands are concerned it is all delivered along that line.

5953. So much so, that past that line you get into the lower sands, and you find no water at all from the upper sands finds its way through, because in the case of other wells which I have just pointed out to you, at Mr. Waterers and at Woking, they had to sink to a depth of 100 feet or more before they found water; so far, therefore, from being saturated with water, very little water passes from the upper sands to the lower. Those wells being so dry, show that there is no large quantity of water, as you would suppose, passing from the upper sands into the lower sands?—I suppose that all the water which falls upon the upper sands is caught by this bed of clay, and is thrown out at certain points all round, and all the water that falls upon that and no more escapes at those points. With regard to the water below that, the wells show the saturated line in that district, and those wells, as far as I have been able to go all round, are not more than 20 feet deep.

5954. The well which is in the lower sands at Woking station is 120 feet deep?—I think that the well in Woking cemetery is only 18 feet deep; the man who made it told me so, and also that it did not vary two feet in winter or summer.

5955. But that is in the upper sands, is it not?—No, that is in the lower sands.

5956. It is just at the base of the upper sands, and goes into the middle sands?—That may be so, but I am not aware of any well in the district which I have encircled, and in the line of the lower catchments, that is deeper than from 14 to 20 feet; if it would turn out otherwise my views on the subject would be very much changed.

5957. You have just mentioned that in Mr. Waterers and the well at Chobham Place, they passed through all three and got no water?—I know the upper sands has no water, but the lower ones hold the water up much nearer the surface.

5958. If you examine those wells, the experience derived from them is not at all favourable with regard to the capacity of the lower Bagshot Sands for holding water?—For yielding water it may be so, but my investigations and inquiries have led me to the belief that the water is near the surface along the line of the lower catchments, and in the pamphlet I have sent to the Commissioners I make the following observations: "At a depth, on the line of the lower catchment, of "about 20 feet below the surface of the sand in the "filtering district, the stratum is saturated with the "water held up by the London clay. This plain of "saturation is now in balance between the amount of "rain water and the resistance it has to overcome in "its downward course to the Thames, and a conduit "sunk in or below this saturated plain would collect "all the water now escaping, in addition to the Thames "water, which may be thrown on the sands, and the "four main collecting conduits shown on the plan are "supposed to be sunk below this line. Its exact level "can only be ascertained by boring, but judging from "the wells in the district, the water of which represents the saturated line, there will be no difficulty "in placing the collecting conduits at such a level as "will effectually cut off the escape of all waters from "the filtering district."

The witness withdrew.

PETER WILLIAM BARLOW, Esq., examined.

P. W. Barlow, Esq.

27 June 1867.

5959. (*Chairman.*) You are a civil engineer are you not?—I am.

5960. Have you turned your attention to the question of supplying London with pure water?—I have, with water from the chalk more particularly. Some 15 years ago when I proposed a plan I believed that the ultimate solution of the difficulty of supplying London would be found in the chalk, and there is nothing which has occurred since to alter my opinion, for reasons which I will explain if the Commission will allow me. I am not prepared with a plan, but the plan which I propose is so simple that it is rather a question of principle than a question of detail. I may mention that in the construction of the North Kent railway I found that large quantities of water were flowing into the river from the chalk on the side, and I was led to look to this from the fact that you have no streams on the surface there. From Lewisham down to the Medway you have only one stream, which in fact gets its source out of the chalk district. Then it occurred to me that there must be a great quantity of water escaping somewhere, and upon examination I found several powerful springs, and one single series of them, which I measured with Professor Anstead, delivered no less in our estimate than 7,000,000 gallons a day; and those series of springs are very nearly all lost before they come to the river.

5961. (*Mr. Prestwich.*) Where were those springs?—At Springhead, near Gravesend, which is known to visitors at Gravesend. There are a number of springs there which become quite a little river, and they are nearly all lost before they reach the river Thames.

5962. (*Chairman.*) Lost in what?—Absorbed in the ground, and they come out again on the sides of the Thames.

5963. Do they go into the chalk again?—Yes. My idea is, that a fault or something of that kind is the means of rendering the soil impervious there, and it throws them up, and they afterwards find their way down again, for they very nearly disappear. I could now measure from actual springs something like 10,000,000 gallons, which is one-tenth of the supply of London, upon that small bit of chalk district, and the amount of district which that represents is not above one-twentieth part of the whole of the chalk district surrounding London.

5964. Do you include the Watford chalk in that district?—Yes; when I say the chalk district I include the Watford chalk; you would have about one-third of the district of Kent on this side of the Medway, or about half as much as there is on the other side. I examined the thing with Mr. Anstead, and we certainly were of opinion that, looking at the experiments which had been made, there would be 60,000,000 gallons a day to be obtained by simply driving a tunnel 20 miles long from Lewisham down to Gravesend, or a little beyond, and I have had no reason to alter my opinion. At the same time there are so many eminent men now, who are opposed to my views, that I fancy I may possibly be wrong about this, but I am unable at present to see that I am wrong. That quantity only represents one-twentieth part of what the chalk would supply altogether; therefore, if you know how to get the water in the chalk, I think you may get a larger supply from it. The question is to know where to intercept the water. I am quite aware that in places you may go and get no water at all; for instance, take Brighton. Brighton is supplied with water from a very small area of chalk, yet close by they sunk a well and they could not get any water at all. The fact is that water does not flow all over the chalk as it is supposed to do in sand, but it goes in certain fissures, and those fissures must find their way to the river or to the sea, and therefore the way to intercept the water is to drive tunnels by the side of the river or the sea. That is the view which I take. The exact direction of the tunnel that I have referred to I do not think is important, except that it should go parallel to the river.

5965. (*Col. Harness.*) You think that the water from the chalk does not find its way to the river on the surface but underneath?—Yes; you do not find the water everywhere on the top, and you cannot expect to find it everywhere underneath. It follows certain fissures in the chalk, and if you know where to look for them or where to intercept them coming to the sea, you are pretty sure,—in fact I may say almost certain,—of a large supply.

5966. (*Mr. Prestwich.*) You would intercept a good deal of what would be the rainfall upon the North Downs as it escapes underground to the river?—Yes.

5967. Can you state what extent of surface that would represent?—The extent of surface on the east of the Medway is 320 square miles, and the infiltration which we reckoned was 8·44 inches, which was the result of experiments made upon a small scale for the purpose of testing it. I believe that the infiltration is really more, but I think it is important to make experiments on a much larger scale than was done. 190 miles, allowing 8·44 inches, would produce 60,000,000 gallons per day west of the Medway, 320 square miles east of the Medway would produce 100,000,000 gallons.

5968. In fact you mean by west between the Medway and Bromley?—Yes.

5969. You stated, did you not, that you calculated upon collecting 60,000,000 gallons a day by means of a tunnel from London to Gravesend or to the Medway?—Yes, a tunnel which will run parallel with the river.

5970. But you could hardly expect to collect the whole quantity, especially that portion which passes off in springs and streams which now flow into the Thames, such as the Cray and the Darent?—This 8·44 inches is assumed to be the amount that is left; the whole rainfall is 26 inches or something of that kind.

5971. (*Chairman.*) Do I correctly understand that you met with a very prolific piece of chalk, and you applied that rule of measurement for a distance of 20 miles, giving a certain result?—No; what we found was the result of 30 miles at the back of it, it was not the production of that particular spot; that spring of 7,000,000 gallons must be the result of a good many square miles of accumulation at the back of it.

5972. What is the basis of your calculation, that you would realise 60,000,000 gallons a day?—Out of the whole rainfall, which is about 26 inches, we get 8 inches.

5973. How do you ascertain that 8 inches would be available as a water supply?—Observations and experiments have been made to show the infiltration, and I have seen the observations of Mr. Robert Stephenson for instance; he made it a much higher amount, and Mr. Homersham considers that it would be a much higher amount than that. There may be an error, and therefore I say that there ought to be experiments to ascertain it more particularly; but assuming that you get half or only a quarter of this estimated amount you have a means of supply which I do not think can be found by any other method.

5974. (*Mr. Prestwich.*) There is evidence, is there not, since your paper was prepared, that several large wells have been sunk along that line, from which a considerable quantity of water is derived?—Yes as regards the East Kent Waterworks; since that time the river which they have to depend upon has, in a great measure, disappeared, and they depend principally upon a well which they have sunk where Mr. Prestwich pointed out that a fault rested, and where they ought to get some water, and they really are getting their supply principally from that very source.

5975. They are getting several million gallons a day from that source, are they not?—Yes.

P. W. Barlow, Esq.
27 June 1867.

5976. Is there not a well at Deptford from which they get 2,000,000 gallons a day?—Yes, I have heard that they have a large quantity in their wells at Woolwich and all the way down, but I do not think that wells are so certain a mode as of driving a heading, because all this water must find its way into the river somewhere between high and low water mark, and therefore I think you are sure to get hold of the greater portion of it.

5977. Did you not notice some strong springs in the river at Erith?—Yes, at very low water you see them.

5978. (*Chairman.*) Are you aware that at Crossness they sunk a well 880 feet deep in the clay and they found no water?—I was not aware of that. They found no water at Brighton, although within a mile and a half they get supply enough by driving headings. I do not think that sinking borings or wells is the way to make sure of obtaining water.

5979. (*Mr. Prestwich.*) Did you ever gauge the Cray or the Dart so as to know what the delivery of those springs is?—I did not, and I forget what they are. One of them receives its water from the outside.

5980. But are there not some strong springs in the valley of the Darent, and you would have to deduct the delivery by those rivers?—Yes, but that would be a very small proportion. You get the floods from the river Dart, which takes its rise in the Weald of Kent, and you get immense floods from the Weald of Kent that go into the chalk.

5981. The Cray rises in the chalk itself, and there is a very strong spring near Orpington, is there not?—There is one river which rises in the chalk, but the Darent rises outside the chalk, and there is one river which flows up to near Sevenoaks, and the floods from there I should say counterbalance that. The floods come down, but they disappear, and there are no floods when you come to the chalk, so that you get the water from the land beyond in addition to the chalk.

The witness withdrew.

Adjourned.

Wednesday, 26th February 1868.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS, C.B.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

J. Quick, Esq.
26 Feb. 1868.

JOSEPH QUICK, Esq., examined.

5982. (*Chairman.*) Which of the metropolitan water companies do you represent?—The Southwark and Vauxhall and the Grand Junction companies, the one on the south side of the Thames and the other on the north side.

5983. In what relation do you stand to those companies?—I am engineer to both of them.

5984. Could you give the Commission the particulars of the supply which the Grand Junction Company derive in the first place, and where they take it from?—I can give the exact boundaries of the supply. The town district of the Grand Junction Company is part of St. James's parish, Hanover Square, Paddington, Marylebone, Kensington, and Hammersmith. Their country district is Acton, Ealing, Chiswick, Hanwell, Brentford, Isleworth, Hounslow, Twickenham, Hampton, Teddington, and Hampton Wick. Those are the districts supplied by the Grand Junction Company. The water is taken from the river Thames at Hampton into subsiding reservoirs, and pumped from there to Kew Bridge, on the Middlesex side of the river. It is there received into depositing reservoirs, and filtered and pumped again from thence to Camden Hill, Kensington, into a high-level covered reservoir, and pumped again to an additional altitude of 150 feet, for supplying the northern portion of Uxbridge Road, Tyburnia, and that portion of the district south of Oxford Street and Bayswater Road is supplied direct from Kew from a stand pipe 220 feet high; so that there are three lifts altogether—in the first place from Hampton to Kew, next from Kew to Campden Hill, and from Campden Hill again it is pumped 120 feet.

5985. What quantity of water does that company supply?—The maximum quantity of the past year has been 8,894,000 gallons per day, and the minimum quantity 7,500,000 gallons.

5986. Have you any means of getting at the population, and showing what that is per head?—The population amounted to 252,927, as far as we could get from the Registrar General's returns.

5987. What would that give per head?—About 34 gallons per head per day.

5988. (*Sir J. Thwaites.*) Is that nett, or do you make allowance for waste?—That is the nett quantity.

5989. When you divide the 8,894,000 gallons by the number of inhabitants is that the average per head?—That is the total quantity, including water for trade and all purposes. The quantity reduced for domestic supply would bring it down, perhaps, to about 26 gallons per head, allowing the difference for trade purposes.

5990. That is to say, eight gallons per head for purposes beyond the requirements of domestic supply?—Yes.

5991. Then the trade supply is not a large item for manufacturing purposes in your district, is it?—Not in the Grand Junction district; not so large as in the Southwark district. There are merely some two or three railway stations, and one or two small distilleries, but very few large manufactories consuming water.

5992. Have you had any complaints in your Grand Junction district as to the insufficiency of the supply?—No, not any that I am aware of. There may be an occasional deficiency, perhaps, in some house on account of some defect in the fittings, or something of that kind, but in a general way I do not think we have any complaint at all.

5993. (*Chairman.*) Have you always been in the habit of obtaining your supply from Hampton?—Since 1852.

5994. Where did you get your supply from before 1852?—At Chelsea, by Chelsea College, as near as possible at the eastern end; then we removed from there to Kew Bridge, and the water was taken at Kew Bridge. In 1852, during the inquiry into the metropolitan water supply, an Act was passed to compel all the companies to take the water beyond the tidal influence, and then it was that we found ground at Hampton suitable for our purpose, and we went up there.

5995. Has there been any result of the change with respect to the quality of the water or the difficulty of getting it?—There has been no difficulty in getting

it, we have an ample supply there, and no doubt the water is much better as there is less contamination.

5996. Has the quality been tested by actual analysis?—Yes; it was proved at the time before the Act passed that the water taken at Chelsea was liable to contamination from the enormous amount of sewage passing up and down the stream, and we were compelled within a certain time, I think within three years, to remove the source of our supply from where the pumping stations existed up to beyond the tidal influence, and Hampton was selected as the most suitable site for that purpose.

5997. Have you any analysis of the component parts of that water?—The water has been analyzed several times, and I think that there would be no difficulty in furnishing the Commission with the analysis.

5998. (*Mr. Harrison.*) It would appear, would it not, in Dr. Frankland's monthly reports?—Yes, it has been printed over and over again.

5999. (*Chairman.*) I understand you to say that you supply about 34 gallons per head per diem, taking the whole of the population, including the trade purposes, and you take off about eight gallons for the trade supply. How long do you imagine that the gross quantity that you now supply will be sufficient for the population?—We have the power of taking to the extent of 20,000,000 gallons a day, and we take rather more than 8,000,000 gallons, so that there is a margin of nearly 12,000,000 gallons within our parliamentary limit, or within the arrangement that we have made with the Thames Conservancy for taking a certain quantity daily.

6000. Have you the means of coming to any conclusion as to when it will be necessary for you to increase your supply beyond what you now furnish?—There is an increasing quantity every year. We find that as we increase our number of tenants so the quantity of water increases. I think that people use more water now than they used to do some two or three years back, for baths and other purposes, and for boilers at the back of kitchen stoves, and a variety of things which are now introduced into houses which were never thought of a few years ago.

6001. Is the population increasing in that district?—Yes, very rapidly.

6002. How long do you think your parliamentary powers will be sufficient; have you the means of arriving at any conclusion upon that point?—I should think that they would be sufficient for the next 50 or 100 years, but it is impossible to say. We are only taking now 8,000,000 gallons out of 20,000,000.

6003. (*Sir J. Thwaites.*) Is that the margin of reserve in respect of the Grand Junction Company, out of the 50,000,000 gallons that have not been utilized?—Yes, each company has the power of taking 20,000,000 gallons, that is, the Southwark, the Grand Junction, the West Middlesex, the Chelsea, and the Lambeth companies.

6004. That is to say, those five companies are taking now 50,000,000 gallons, and they have statutory power to take to the extent of 100,000,000?—Yes, so that we are taking something less than one half of our statutory power.

6005. (*Chairman.*) Supposing that you wanted a greater quantity than that, is it your opinion that the basin of the Thames would be able to supply it?—I think there is no doubt of that. The lowest gauging that has ever been taken of the Thames has amounted to 360,000,000 gallons in 24 hours. The average is something like 600,000,000, and in time of flood it is more than 50 times that quantity.

6006. Where has this gauge to which you refer been taken?—It has been taken at Teddington lock.

6007. (*Sir J. Thwaites.*) Have you the mean gauge?—No, I have not. The average I should say would be something like 600,000,000 gallons a day.

6008. (*Chairman.*) Supposing it were necessary to increase the supply, you say that the Thames basin would be able in your opinion to supply it; in what manner would you collect it?—If it were necessary, large storage reservoirs might be provided in the upper Thames; but as we only take now one-seventh of the minimum flow, it would be a long time before anything of that kind would be required.

6009. And the quality of the water you say is good?—It is very good indeed for all purposes, not only for domestic purposes but for manufacturing purposes. Brewers and tanners, and those people who use large quantities of water for trade, all prefer the Thames water to any other water that they can get.

6010. What other water could they get?—Well water from artesian wells and rain water. They come to the companies now even for water for condensing purposes for engines.

6011. As the engineer to those companies, have you turned your attention at all to the system of constant supply at high pressure?—There is a clause in the Act of 1852 making it compulsory on the water companies to give a constant supply if certain things are carried out by the inhabitants.

6012. Are those certain things being carried out?—I do not think there is any change in that respect being carried out.

6013. What are the things that are required to be done by the inhabitants?—Putting all their house fittings in such order as to prevent the waste of the water, and that would involve such an extraordinary amount of outlay, particularly in the poorer districts, that I do not think there is any probability of the public ever doing anything of the kind to carry it out.

6014. Do you think that it would be a good thing?—I think that in the poorer districts it might be an advantage, but I think that practically the better class houses have the best constant supply that they can have by having a good cistern in their houses, by means of which, in the event of any interruption from the breaking of a main, or a conflagration in the neighbourhood, or anything of that kind, they have a supply of water which will last them two or three days in their own cisterns; whereas if they merely depended upon a pipe passing into the house, the moment that there was any interruption to the flow in the main they would be deprived of that accommodation.

6015. Then are we to infer that you are not in favour of the constant supply system?—I think that it has its evils. Perhaps in a poorer neighbourhood it might be an advantage, but I think where cisterns are properly taken care of and cleansed, and so on, that is the best constant supply that anyone can have. In fact, I do not know how the constant supply is to be arranged in a house, where the kitchen boilers, for instance, require constant filling; and with regard to waterclosets, again, it would be an exceedingly inconvenient thing to have water absent from the house probably for 24 hours in the case of an accident to a main, or anything of that kind.

6016. (*Sir B. Phillips.*) Are the accidents to the mains of which you speak frequent?—The large valves want repairing occasionally, and the mains will break now and then, and alterations are necessary, such as putting on new branches to a main, and when the main has to be cut out and a connexion made to it to go down a side street during the whole of that time, which may occupy several hours, if there were no storage the people would be deprived of water.*

6017. (*Chairman.*) Could you not have both the constant supply and the storage system also?—I do not think there would be any advantage in the constant supply, because virtually it is a constant supply now if they have proper cisterns.

6018. (*Sir B. Phillips.*) Then there is at present a form of constant supply to the better-class houses?—It is so where there is a good cistern in the house, the cisterns being filled every day; if they hold anything like 200 or 300 gallons, or whatever it may be that is necessary for the use of the house, they have it at hand.

* See statement at end of evidence.

J. Quick, Esq.
26 Feb. 1868.

6019. (*Chairman.*) When cisterns are put to houses I presume it is with a view to their containing at least 24 hours' consumption?—We always advise them to put cisterns for 48 hours' consumption, and in most of the better-class houses they even go very much beyond that.

6020. That would be then, as you say, practically a constant supply?—That is a constant supply, practically; and we now, both the Grand Junction Company and the Southwark and Vauxhall companies, give a Sunday supply, in addition to the ordinary week-day supplies, in several of the poorer districts, so as to endeavour to meet the requirements of the public in every way that we can.

6021. Then if the cistern system, which in point of fact is a constant supply, is the one which your company recommends to the better-class houses, giving them two or three days' consumption, and you think that the other system of constant supply would be an advantage in the poorer districts, you are in favour, are you not, of a constant supply in London?—I think it would be an advantage to the poorer districts; but it would be accompanied by an enormous amount of outlay to accomplish it.

6022. In what way would that outlay be rendered necessary?—From the present state of the house fittings in the poorer districts; if any more pressure were put upon the pipes, and taps, and valves, and things of that kind, they would all fly to pieces; the pipeage is weak, and the taps are imperfect, where there are taps, and if they were not put in proper order the waste would be so great that there would not be any pressure at all; the water would all run down the drains, and in the higher portions of the district they would never see any water at all.

6023. Do you think the expense of putting them in proper repair would prevent its being carried out?—We find great difficulty in getting the owners of small property to lay out a single sixpence for benefitting their tenants in any way, and I am quite sure that any representation that the companies could make would never induce them to do it unless there were some legislative power to compel them.

6024. Does your company supply one sort of water to all consumers, trade and streets and private individuals?—Yes, it is all filtered exactly in the same way and pumped from the same source. There is not any difference at all; it passes through the same trunk mains, and is divided out into the various pipes.

6025. Would there be any advantage in your having two sorts of water?—It would involve a double system of pipeage, which would be attended with enormous expense. The company now have 360 miles of pipe in constant operation.

6026. (*Col. Harness.*) Do you deliver any water through meter?—To some of the trades we do, but not for general consumption; it is found too expensive an operation for small purposes, that is say, for ordinary house supplies.

6027. (*Sir J. Thwaites.*) When you speak of constant supply is it not admitted that in the case of houses of a certain class, with closed boilers for example, for supplying baths and for other purposes, you must, under any system, have a cistern for the purpose of preserving sufficient water to keep in action those arrangements?—Yes, under any system.

6028. I apprehend that the number of houses of that class, as compared with the number of houses in the metropolis, would be very small, would it not?—Not in the Grand Junction district; in the whole of the new portions of the Grand Junction district they have appliances of that kind in their houses; in fact, I should think in two-thirds of the houses. They supply a district from the east side of the Haymarket, the north side of Pall Mall, in a straight line up to Oxford Street, taking in all the great squares, and up as far nearly as Kilburn Gate in the Edgware Road, and then westward again, so that they take in a very fine district—one of the best districts in London as far as property is concerned.

6029. Has your attention been directed to the principle of a constant supply in regard to its effect upon the public health?—I think, as I have stated before, that in the poorer districts there would be a great advantage from the constant supply, but in the better class of property I cannot conceive that there would be any advantage at all in respect of health.

6030. Do not you think that the principle of storing water in cisterns, whether well or ill constructed, has any effect upon the health of the inhabitants?—I do not.

6031. A constant supply would have its advantages for the purposes of fire, would it not?—I think there is a great question whether it would or not.

6032. I mean under proper pressure?—That is the difficulty. If there are so many thousands of taps in connexion with the mains, there will be always a certain amount of draught passing into the district which will lower the pressure. At the present time the whole of the trunk mains or principal mains of the district are kept under the full pressure all night, and in case of fire they have only to open one of the side cocks and direct the water to the particular place where the fire may be burning, and all the pressure can be directed by merely opening these one or two cocks, whichever it may be.

6033. But I wish you to direct your attention not to such a pressure as that the fires might be extinguished from the hydrants by application of the hose, but to such a pressure as would keep the pipes charged and the supply sufficiently full to be pumped by means of a separate fire engine.—That can always be done by the mere opening of one of the side cocks leading from the trunk main.

6034. The difficulty now is to find water, is it not, in case of a fire?—The water is always in the main.

6035. A recent case occurred where water was not to be obtained in any quantity for useful purposes for more than 20 minutes after the fire, and the destruction was pretty well completed, how do you account for that?—I think that that arises principally from the a want of understanding between the brigade and the water companies.

6036. It arose from the fact of there being no water in the main, and would not the constant supply under an ordinary pressure (I am not speaking of high pressure) have prevented that state of things?—Yes, if the water had been in the main but it might have happened that the main was severed at the time by some repair or some alteration, but I do not know the circumstances.

6037. There was no repair or anything of that kind?—Then I cannot conceive how it could have been; but if there were a proper arrangement that when a fire is reported at the fire station they should despatch a man to the turncock of the district, in 99 cases of 100 the water would be at the fire before the engines arrived, but unfortunately the brigade will not take the responsibility of calling the turncock, and we cannot bring about any arrangement of that kind; we pay any amount of rewards, or anything of that kind, but it is of no use, they will not do it.

6038. Without discussing that question, I would just confine your attention to the question of constant supply, as compared with the present intermittent system; would not a constant supply as a general rule give greater facility for the suppression of fire than the system now prevailing?—There is no doubt that if the water were always in the services it would be so, but the water now is in the whole of the trunk mains of the company, and the services are merely shut off by the closing of a side cock after the general service of the day, whatever it may be, is over. If it is on from 12 to 3, or whatever time it may be, the cock is then shut down, the trunk main having the full pressure during the whole of the night or the remaining portion of the 24 hours.

6039. Then it is shut off, according to your own acknowledgment, from the mains that would be used for the purpose of supplying water for suppressing fires?—The whole of the side services are shut off.

6040. What would you say if it frequently occurred

that the turncock could not be obtained in less than 20 minutes from the time that the fire had been discovered?—If it is necessary to obviate that in any way, we undertake to furnish any amount of tools to the fire brigade, to teach them the position of all the cocks in the district, and to give them any amount of information that we can, and I think that we can ensure a full pressure into any side service by the present means; whereas if the water were left all over the district, in the place of having a head of 50 or 60 feet, which we may get now in a very few minutes, it might be reduced perhaps to 10 or 15 feet.

6041. Would not the very simple process of filling all the pipes be very much better than the present complicated system, liable to delay as it is in working?—If you could do away with the waste from the lead pipes leading into the houses, there would be no difficulty in leaving the whole district open.

6042. My question has reference now not to high pressure, but to a sufficient pressure to fill the service pipes. — Practically that would interfere so much with the general working of the district, that we should not get any water at all into the cistern in certain portions of the high districts if we were to allow all those side services to be open.

6043. (*Chairman.*) How is the water that is consumed at fires paid for?—It is not paid for at all, the companies afford it gratuitously.

6044. (*Sir J. Thwaites.*) You have spoken of a clause in the Act of Parliament which gives the right to the inhabitants to demand a constant supply on certain conditions; that is to say, certain things must be done by the inhabitants to give them a *locus standi* to call upon the companies to supply under constant pressure; is it not generally understood that that clause was arranged with the water companies, they professing on the one hand to give that right to the public, but the complication of conditions was such as to render it utterly nugatory?—The companies have never objected, and would never object to give the constant supply if the public would fulfil the obligations of that clause.

6045. Are not the obligations of such a character, and the parties to determine the merits of the application so interested in the supply of water, that it is utterly impossible to put that clause into action?—I cannot conceive that it is utterly impossible to put it into action, it is merely this, that every one is to put his pipes and taps into such order as to prevent waste.

6046. Are not the water companies made the judge of that?—The requisition must be from four-fifths of the tenants or owners of houses on a district main, and certainly the companies are left to judge whether the pipes are in proper order or not.

6047. Are not the arrangements of such a character that they must be approved of by the water companies, and that four-fifths of the occupiers or owners, or whatever the proportion may be, shall comply with those conditions?—Yes, that is so.

6048. Then if the water companies were to allege that the parties had not sufficiently carried out their obligation in strengthening their pipes and arranging the apparatus generally, the water companies could still refuse to supply on the constant system?—I think that there is an appeal to two magistrates or to the Board of Trade to decide what the proper fittings are.

6049. What is the clause by which you say a constant supply is compulsory upon the company upon certain things being undertaken by the owners of the houses?—The 15th and 16th Victoria, chapter 84, section 15: "After the expiration of five years from "the passing of this Act every company shall, subject to the provisions of the special Act relating to "such company, provide and keep in the district "mains already laid down, or hereafter to be laid down by them, a constant supply of pure wholesome water sufficient for the domestic use of the inhabitants of all houses supplied by such company, at such pressure as will make the water reach the "top storey of the highest of such houses, but not "exceeding the level prescribed by the special Act of "such company; provided that no company shall be "bound to provide a constant supply of water to any "district main until four-fifths of the owners or "occupiers of the houses on such main shall by "writing under their hands have required such company to provide such supply, nor even upon such "requisition, in case it can be shown by any company "objecting to the same that more than one-fifth of the "houses on such main are not supplied with pipes, "cocks, cisterns, machinery, and arrangements of all "kinds for the reception and distribution of water, "constructed according to the regulations prescribed "by the special Act or by this Act, or which any "company with the approval of the Board of Trade "may from time to time make in that behalf."

6050. (*Chairman.*) Four-fifths of the tenants or owners in the district are required to put their fittings into proper order to take the constant service, and then having done so, you would be required, would you not, to supply them in the manner required by the Act?—Yes.

6051. (*Sir B. Phillips.*) Would that be a very expensive process?—It would be a very expensive process to the owners of property.

6052. Have you any idea what it would cost per house?—It depends upon the class of house, in some cases it might cost 2*l.* or 3*l.*, and in others 10*l.* or 15*l.* per house.

6053. It would depend, would it not, upon the size of the house and the quantity of water required in it?—Yes, and the position of the supplies in the house.

6054. (*Sir J. Thwaites.*) Is it not quite as I have put it, that after the part of the clause pointing out how many inhabitants must agree and subject to the final approval of the Board of Trade: "It shall be "lawful for the surveyor or any other person acting "under the authority of the company, between the "hours of 9 of the clock in the forenoon and 4 of the "clock in the afternoon, to enter into any house or "houses on such district main in order to ascertain "whether the pipes, cocks, cisterns, and machinery "of such house and houses are so constructed as aforesaid; and provided also that any company may "with the consent of the Board of Trade suspend the "giving of such constant supply." So that you are really made the judge as to whether the alterations required by the Act are satisfactory or not to the company; therefore, if you who are made the judges were disinclined to carry out this arrangement, might you not urge such objections as should make this professed advantage on behalf of the public a nullity?—I do not think that there is the slightest disposition on the part of the companies to do so. I am sure that the companies would be very glad to comply with the requirements of that clause, if the public would do their part to prevent the waste of water.

6055. (*Col. Harness.*) How do you define a district main; it might be small or large, might it not?—It is a very difficult question to answer, but I look upon a district main as a main branch that the turncock may command by one stop cock. It may have many ramifications, but they would be commanded by that one stop cock.

6056. And a very large population may depend upon it?—That may be so.

6057. (*Mr. Harrison.*) Can you state to the Commission without any difficulty what would be the cost of raising say 1,000 gallons or 1,000,000 gallons 100 feet high?—In the case that I have just been mentioning the water is pumped three times over. It is pumped first at Hampton to an elevation of 94 feet, then it is pumped at Kew to an elevation of 200 feet, and then at Campden Hill to 150 feet; so that to raise it 100 feet is only part of the expense to the company.

6058. You do not know what the expense of the first rise is, the raising in to Camden Hill?—I do not know that at present, but I can furnish the Commission with it no doubt. (*See Appendix K.*)

J. Quick, Esq.
26 Feb. 1868.

6059. Have you found that the quantity consumed per head has been going on by any regular 'progressive increase for many years?—It has been going on gradually increasing from year to year, and still goes on.

6060. Looking forward to a few years hence, what is your view of the probable quantity per head that you ought to calculate upon?—We find that by employing one or two inspectors to go round the district, and to check the waste as far as we can without causing any distress to the tenants, we can reduce the quantity even that we are pumping now, therefore I do not think that for some considerable time to come there will be any very great increase; because if the companies will only go to the expense of putting on some few extra men to check the waste by calling upon people to put their taps, and so on, in a proper state of repair, the quantity now pumped ought to be very much reduced.

6061. In making an estimate in such a case as that which we are now considering, what, from your experience, should you say would be a safe quantity per head to calculate upon?—I should think 30 gallons per head would be the very outside that there ought to be supplied, and that is about the quantity now given to the whole metropolitan area. It is as near as possible 29¾ or roundly 30 gallons per head.

6062. Is not the greater portion of the district that you supply occupied by the better class of population?—Yes, in the Grand Junction district it is so.

6063. Do you find there that the consumption per head is much larger than in the poorer districts?—Yes, very much larger, and that arises from the conveniences that people have in the better-class houses, namely, boilers, baths, and water-closets, and matters of that kind.

6064. You supply the water in Westbourne Terrace, do you not?—Yes, we do.

6065. Have you found within the last month or two that there has been a complaint of the colour of the water?—Yes, during the heavy floods, the water was perfectly bright, but there was a strong colour in it.

6066. Was that merely arising from the floods?—Yes, it was merely arising from the floods, the washings of the clay from the Oxfordshire hills generally imparts a certain amount of colour to the water.

6067. At the present moment that colour is nearly gone, is it not?—I think it is quite gone; it has been gradually getting better from day to day.

6068. That is not a usual occurrence with your water, is it?—No; sometimes we do not see anything of the kind for three or four years, but it has been more tinged during the past month than I have ever seen it before.

6069. (*Sir J. Thwaites.*) Is that after filtration?—Yes, it is after filtration. It is the colour which filtration will not take out; it is a stain in the water. The water is perfectly bright and pellucid, but it has a decided tinge of yellow in it.

6070. (*Mr. Harrison.*) In the present system of supply, is it not one of the great objections to the cistern system that those cisterns are not kept clean by the owners of the houses themselves?—That is so.

6071. And if they got the water direct from the pipes, they would get it, would they not, in a purer condition?—There is no doubt of that.

6072. Your view perhaps would be that it would be a necessary thing to have a combination of cisterns and a supply direct from the pipes in the same house?—Yes.

6073. Up to the present time the practical effect of the clauses in that Act of Parliament has been, has it not, that no company has been called upon by the inhabitants to give them a constant supply?—That is so.

6074. Do you think that the water companies themselves would object to it if they were called upon by the inhabitants, and if the inhabitants were to do their part of the duty?—I do not think they would. Of course the water companies would have to lay out a very large sum of money to enable them to do it, and I had perhaps better explain why that would be so. It is on account of the undulations in the districts. In the Grand Junction district there is some portion of it but little above the level of the Thames, whereas other portions are nearly 200 feet above the level of the Thames, and it is constantly rising and falling; and of course if the water is allowed to run to waste in any way in the lower portions of the district, unless there is a division of the trunk mains the high portions would never get any water at all.

6075. Still there would not be an objection on the part of the companies to that outlay?—I think not, if proper provisions were made.

6076. And it would necessarily be attended with much greater stringency of supervision on the part of the water companies?—Yes.

6077. Do not you think that the result would be great economy in the consumption of water per head?—There might be an economy in the quantity of water pumped, but the difference of cost to the companies would not be any very great deal. You would not reduce the expense of management, or labour, or anything of that kind; it would be the mere expense of pumping.

6078. Still there would be economy in the actual consumption per head?—Yes; there is no doubt there would be less water used, supposing that all the fittings were put in a proper state to prevent waste.

6079. You have been connected with the water companies of London from almost the earliest time, have you not?—I have been connected with them a long time.

6080. (*Col. Harness.*) What part of your district is dependent entirely for a high-level supply on that lofty stand pipe of which you have spoken?—The whole of the district north of the Uxbridge Road, up as far as Kilburn Gate.

6081. Then I presume in that district the pressure in your mains is maintained by keeping the stand pipe full?—Yes, by keeping the stand pipe full, and always pumping the water up to that level.

6082. Have you your engines going at night?—Yes.

6083. (*Mr. Prestwich.*) What do you estimate to be the waste under the present system of supply?—I should think nearly one-third of the quantity pumped.

6084. That is to say, out of 34 gallons per head you would estimate that 11 or 12 gallons are lost?—Yes.

6085. (*Sir J. Thwaites.*) I understood you to state, in answer to his grace's question, that the average supply would be 34 gallons per head per diem, but that the actual supply finding its way to a house for domestic purposes would be about 26 gallons; is not that so?—Yes.

6086. That is reducing it by eight gallons?—Yes.

6087. Am I to understand that the waste out of 34 gallons is 12 gallons?—Yes, I have no doubt of it.

6088. Then you are taking away 12 gallons and eight gallons from 34 gallons, leaving 14 gallons for domestic purposes?—34 gallons is the entire quantity of water pumped by the company, and distributed to a certain number of inhabitants.

6089. Thirty-four gallons per head is the gross quantity pumped, and you say that then out of that 34 gallons the waste is 12 gallons; then for street and trade purposes you have another 8 gallons, that is 20 gallons subtracted from 34, leaving for domestic purposes 14 gallons per head only?—Yes, 14 or 15 gallons. I have no doubt that is the quantity; and if you take the consumption in some of the large northern towns of 21 or 22 gallons, including trade purposes, it comes to about the same thing.

6090. That is to say, if you have any other supply than the supplying of private houses, 14 gallons per head, if you could deliver that quantity, would be ample for all purposes?—Yes, I should say 14 or 15 gallons without waste would be ample.

6091. (*Chairman.*) Now you have 14 or 15 with waste?—It is 14 plus the waste.

6092. (*Sir J. Thwaites.*) Have you any idea, or

J. Quick, Esq.
26 Feb. 1868.

does your experience confirm that view of the case that a constant supply would be a saving of water?—No, it all depends upon the amount of supervision, because unless people are very careful indeed in not allowing the taps to leak or the water to run to waste, the supply might be very much in excess of what it is now with all the waste.

6093. Supposing that there were an ordinary amount of inspection by the companies to see that the arrangements are such as not to admit of waste, would not the principle of constant supply result in a saving of water, and prevent the waste which now occurs by persons tying up the balls and permitting the water to run during the whole time that it is on in the main?—I think that is the great question. If everything was put in the most perfect order that it could be, there is no doubt there would be a considerable saving beyond the present quantity pumped; but it all depends upon the amount of supervision and the more or less perfect state in which the fittings are maintained.

The witness withdrew.

The witness subsequently sent in the following statement to illustrate his answer to question 6016. He adds "In nearly all these cases it was found "necessary to keep the stopcock on the main or "service pipe short during the carrying on of the "work, for periods varying from 1 to 24 hours."

SOUTHWARK AND VAUXHALL WATER COMPANY.

A DETAILED ABSTRACT showing the Number and Nature of the different Works performed in this Company's District during the 12 Months ending 31st December 1866, which would have occasioned Interruptions in the Supply of Water to the Tenants, supposing such Supply had been constant instead of intermittent.

WILLIAM RICHARD MORRIS, Esq., examined.

W. R. Morris, Esq.

6094. (*Chairman.*) What metropolitan water-company do you represent?—The Kent Waterworks Company.

6095. In what relation do you stand to that company?—I am the engineer.

6096. Can you state the area that the Kent Waterworks Company supply?—I cannot; I am not prepared with it at this moment. We have made some very large additions within a very short period, and I do not know the total quantity of area. I know the total number of houses.

6097. Can you describe the district?—The district extends from Camberwell to Dartford in one direction and from the river Thames to Chislehurst and Bromley in the other.

6098. But you cannot give us the area?—I have not calculated out the quantity. A portion of this district is very new to us now, and I am not prepared to say what the exact area is.

6099. From whence do you draw your supply?—The whole of our supply is from deep wells in the chalk at various points. We have wells at Deptford, at Charlton, at Plumstead, at Crayford, and at Bromley.

6100. Is the Ravensbourne in your district?—Yes, the Ravensbourne is a small river which formerly fed our works.

6101. Do you mean that you have ceased to take water from the river Ravensbourne?—Yes, we have abandoned the Ravensbourne, and we pump wholly from artesian wells.

6102. How long is it since you have gone to artesian wells for a supply?—During the last six years our supply has been entirely from artesian wells.

6103. What was the cause of your giving up the Ravensbourne and taking to those wells?—I believe the principal cause was that we had exhausted the contents of the river. The flow of the river was completely absorbed by our works, and we were necessitated to find other water. We were guided in that respect by the recommendation of a former commission upon this subject, who strongly recommended chalk water.

6104. What is the quality of the water?—The quality as compared with the well water of the district is soft; as compared with rain water it certainly is hard. It is rather harder than the Thames water.

6105. You have mentioned that you went to deep wells for your supply in consequence of the report of a commission. To what commission do you refer?—The commission that I speak of was in 1851, and was composed of Professors Graham, Miller, and Hoffman.

6106. I see by a return that your water is of the hardness of 27·3 degrees, as compared with the river Lea 18·2?—Probably it is so.

6107. And the sewage contamination of yours is ·4220 as against the river Lea ·2950?—I totally deny that as a fact, and I do not believe that any other person but Professor Frankland would venture to assert it. Indeed, Professor Frankland himself seems to have various opinions upon the subject from time to time. When Professor Frankland has reported the Lea as containing no previous sewage at all in it last August, and the deep wells at Grays as containing $8\frac{1}{2}$ per cent., there must be some misunderstanding as to the terms.

6108. Have you any analysis of your own water?—I have not an analysis of the whole of the wells, but on the subject of sewage contamination I beg leave to hand in this statement of Dr. Letheby:—

W. R. Morris, Esq.

26 Feb. 1868.

LETTER addressed to the Directors of the Kent Water-Works Company by Dr. Letheby, Professor of Chemistry, &c. &c.

In the weekly Report of the Registrar General for the week ending Saturday, May 4th, there is a statement to the effect that "The Kent water is altogether the worst sample of the eight," that is, of the water supplied by the eight water companies of London; and this opinion is founded on the Report of Dr. Frankland, which, under the head of previous sewage contamination (estimated), gives 3195 parts of sewage in 100,000 parts of water, which is a little more than 3 per cent.

Having made very careful analyses of the Kent water, month by month, for the last three years, and having failed to discover, at any time, the least trace of what can be termed sewage contamination, and having, moreover, made two analyses of the Kent water in the very month to which the Registrar General's remarks apply, I was surprised to find it stated that the Kent water was, in all respects, the worst kind of water supplied to the metropolis.

So far is this from the case, that every month for the last two years I have reported to the Association of Medical Officers of Health of London, that the amount of organic matter contained in the Kent water is so insignificant as to be hardly discoverable by the most refined processes of chemical research; when, for example, the water is examined in a long glass tube, it is found to be as blue and free from organic tint as distilled water; and when it is tested by means of an oxydising agent (permanganate of potash), the amount of oxygen required to oxydise everything in it of an oxydisable nature, does not amount to the one-hundredth part of a grain per gallon of water: in fact, the average amount of organic matter in the Kent water for the last twelve months does not exceed the tenth of a grain per gallon, or one part of organic matter in 700,000 parts of water; and during the very month referred to in the Registrar General's Report, the quantity of organic matter in the sample which my assistant took from a main pipe at New Cross was so small as not to be capable of estimation.

How then are these discrepancies of opinion regarding the quality of the Kent water to be reconciled? This is easily done by considering that the expression used by Dr. Frankland, as regards a supposed previous sewage contamination, is but a figure of speech; and however alarming it may be to those who have no knowledge of its true signification, it really means no more than that at some time in the world's history, perhaps in an antediluvian period, a hypothetical quantity of organic matter had been deposited; and that in subsequent time the water, while percolating and slowly finding its way through the fine fissures of the chalk, had dissolved the animal matter, which had then undergone such a thorough change by oxydation as to leave its mark in a scarcely discoverable amount of combined and harmless nitrogen. The change indeed of this so-called previous sewage contamination is as complete and as salutary as that which occurs within the growing plant in the transformation of manure into food: and it would be just as true and as pertinent to say that the nitrogen in the bread which we eat represents a certain amount of sewage contamination. Unfortunately, these exaggerated views of the pure chemist, when contemplating the facts of pathological or physiological science, are apt not merely to alarm unnecessarily the public mind, but they offer serious impediments to the progress of sanitary knowledge, and also weaken the confidence of the public in the usefulness of protective medicine.

Let me then, in conclusion, give you the most positive assurance that the water supplied to the public by the Kent Waterworks Company is not only free from sewage contamination, but is in all respects a good and wholesome water: so little indeed is it tainted with organic matter, that it offers in this respect a striking contrast to the highly-praised soft waters of Cumberland and Wales.

(Signed)
HY. LETHEBY, M.B., M.A., Ph.D., &c. &c.,
Professor of Chemistry in the College of the London Hospital and Medical Officer of Health for the City of London.
17, Sussex Place, Regent's Park,
18th May 1867.

And again on the subject of the well at Bromley on the same point there is another very recent report which I will hand in.

REPORT of an Examination of Water from the Wells at Shortlands, one of the Pumping Stations of the Kent Waterworks Company.

On Thursday, the 9th instant, I visited Shortlands with Mr. Morris, the engineer of the company, and took samples of water from the *deep well* which supplies the works, and also from a disused *bore-hole*, which receives surface water.

I observed that the water from the deep well was pumped from a great depth through an iron cylinder, which had no communication with the surrounding surface water that stood at a much higher level in the outer cylinder, and which was wholly unaffected by the pumping operation. Mr. Morris informed me that the cylinder through which the water was pumped was perfectly water-tight, and that it passed through 60 feet of clean fine sand and 10 feet of marl into the chalk, the well being carried to a further depth of 180 feet into pure white chalk, thus making a total depth of 250 feet from which the water is supplied.

The character of the district in which the well is situated is open and free from habitations; in fact, there were no apparent sources of pollution for even the surface water; not only is there a considerable distance between Bromley and Shortlands, made up of materials which are notoriously powerful as purifiers of water, but there is also an impervious layer of clay, 10 ft. in thickness, between those strata and the chalk, through which the surface water cannot pass. As, however, I considered it desirable to ascertain the quality of the surface water, as well as that of the deep well, I requested to be furnished with water from the bore-hole, which is only a short distance from the well, and which is open to surface percolation. In this manner I obtained, under my own immediate observation, samples of water from the deep well and from the bore-hole.

Both of these samples were perfectly bright and colourless even when examined in large volume, as in a glass tube two feet in length. They were also cool, sparkling, and agreeable to the taste.

On being analysed for ammonia with the view of ascertaining if they contained a trace of decomposing organic matter, it was found in each case that the proportion of ammonia amounted to only 0·0036 of a grain per gallon, of one part in nearly 19,500,000 parts of water, and the minute proportions of organic matter in the water yielded, in one case, only one part of ammonia in 50,000,000 parts or water, and in the other, one part in about 27,000,000 parts.

Tested in another way, it was found that the organic matter required only 0·05 of a grain of oxygen per gallon for the deep-well water, and 0·1 for the bore-hole water.

The mineral constituents of the two samples were very nearly alike, and were as follows:—

	Deep well water. grains.	Bore-hole water. grains.
Carbonate of lime and magnesia	14·85	15·75
Sulphate of lime	2·13	2·52
Alkaline chloride (common salt)	0·90	0·90
Nitrate of lime	1·86	0·80
Silica and alumina	0·53	0·73
Total per gallon	20·27	20·70
Hardness	17·0°	17·0°
Ditto after boiling a quarter of an hour	3·5°	4·0°

Lastly, experiments were made for the purpose of ascertaining if the water acted on lead, and the results were negative and therefore satisfactory.

The conclusion from these investigations is, that the water derived from the deep well at Shortlands is good and wholesome; that it is not only remarkably free from organic impurity, but is also less than usually charged (considering it is chalk water) with saline matter; and I have no hesitation in saying that it is in all respects a good and wholesome water, and fit for domestic purposes.

I am also equally satisfied with the results of the examination of the water from the bore-hole, for although it is, in all probability, largely charged with surface water, yet it does not exhibit a single property that renders it all unsafe for domestic use; and even if it were so, its quality would in no way affect the water derived from the deep well.

(Signed) HY. LETHEBY, M.B., M.A., Ph.D., &c.
Professor of Chemistry in the College of the London Hospital, and Medical Officer of Health and Chemical Analyst of the City of London.
College Laboratory, London Hospital,
January 30, 1868.

To the Directors of the Kent Waterworks Company.

I have also made a report of my own upon the same subject, making three reports on the point, and it is as follows:—

COPY of a LETTER addressed to the Bromley Local Board of Health by the Engineer to the Kent Waterworks Company.

Kent Waterworks,
SIR, February 10th, 1868.

I ENCLOSE copies of Dr. Letheby's Report on his special examination of the water supplied to Bromley from this company's works at Shortlands.

The accuracy of modern chemical analyses leaves little

room for difference in the determination of the mineral and other constituent parts of water, and a comparison of Dr. Letheby's examination with that of Dr. Frankland, as reported by the Registrar General, will show that this is not so much a question of analysis as upon the accuracy of the comment and the truth of the deductions.

Following the figures from the Registrar General's Report indicating the amount of "previous sewage contamination" in water from the Kent Waterworks Company's wells at Deptford and Shortlands, and from the South Essex Company's wells in the chalk at Grays, we find it alleged that in each of these cases the waters have a far greater proportion of sewage than the Thames. The figures presume that every 100 gallons of water from Shortlands well has a mixture of 4¾ gallons of London sewage, or its equivalent; and as the chalk rock at Shortlands would yield a supply quite equal to that of the company's wells at Deptford (5,000,000 of gallons daily), it would follow, that on using the Shortlands water to its fullest extent it would be equivalent to pumping therefrom 240,000 gallons of sewage in its most offensive sense. There is no avoiding this absurd conclusion on Dr. Frankland's assumption: this taint of sewage on this hypothesis extends to every spring that issues from the chalk in the county, and to every town deriving its supply of water from the chalk formation. The explanation of this mere figure of speech, "previous sewage contamination," will be found in Dr. Letheby's Report on the subject, which I enclose.

The Government Commission of 1851 of Professors Graham, Hofmann, and Miller, recommended in the most earnest manner the chalk as a source for future London water supply.

Dr. R. D. Thompson, the predecessor of Dr. Frankland, in his Cholera Report of 1856 urged that this water is not subject to contamination by organic matter; and even if rain water, the primary source of this aqueous deposit, should convey any matter from the surface, the chalk would oxydize the organic matters and convert them into new and inert forms.

The Board of Trade in 1860, through Captain Galton, who examined the Kent Company's water supply, assisted by Professors Abel and Miller, urged the completion of the scheme of supply from the chalk then in progress by the company.

Finally, during the last session, a committee of the House of Commons inquired into the London water supply: the Metropolitan Board of Works attended and represented the public, but no objection was taken to the purity of the Kent Company's water, on which the Committee made a favourable report.

The well at Shortlands is sunk to a depth of 340 ft. below the ground on which Bromley stands; it is formed with double iron cylinders, the outer cylinder enters the chalk at the depth of 70 ft. (160 ft. below Bromley), the inner cylinder is continued considerably deeper, and is bedded firmly in the chalk: to ensure sound work the lower portion of the work was executed by divers under 60 ft. of water; the test of the perfection of this work is the difference of level that exists between the two cylinders when the engine is pumping, the level of the outer cylinder water remaining unchanged while the water sinks under the operation of the pump in the inner cylinder. This care was taken to exclude effectually the surface water, though from Dr. Letheby's analysis the surface-water itself does not appear to possess any injurious quality.

I place these facts in opposition to Dr. Frankland's theory, and I regret that that gentleman has not personally inspected the works, or even assured himself that the samples of water obtained for analysis were collected with due precaution to ensure purity. I think such a visit would have spared me this explanation, and the public would not have been needlessly alarmed.

I shall be happy to attend at any time your Board may wish and give any further information on this subject they may require.

I am, sir, your obedient servant,

W. R. Morris,

Engineer to the Kent Waterworks Company.

To R. Latter, Esq.,

Clerk to the Local Board of Health, Bromley.

6109. (*Sir J. Thwaites.*) When you say that Dr. Frankland is the only person who would venture to make such a statement as that which you have given us, namely, as to the degree of hardness and the degree of impurity, do you suppose that Dr. Frankland has any special prejudice against the Kent Company?—I think you misunderstand my words. My words apply only to the previous sewage contamination. The previous sewage contamination by Dr. Frankland is estimated upon the amount of nitrates in the water. I say that all other chemists tell you that the nitrates have other origin than sewage, and as applied to chalk it is not only in fact impossible that sewage could arrive at the water, but it is wrong data altogether.

6110. Do you consider that there is not so much reliance to be placed on the analysis of Dr. Frankland as upon that of Dr. Letheby?—I do not think that there is any material difference at all in the analysis, but simply in the comment upon it. Having analyzed it, Dr. Frankland says that the nitrates have a sewage origin; but I say that it is not necessary that it should be so. Besides, Dr. Frankland at the commencement of this year had one theory, but he has now changed it for another.

6111. (*Chairman.*) One of the theories is that the maximum solid impurity is 41·74, as against the river Lea 26·60; is that a theory, or is it correct?—I believe that is quite correct. Impurity there must not be taken in the popular sense of the word; it means the mineral and other constituent parts of water. If you take it in the popular sense as meaning dirt, it does not mean that, nor does Dr. Frankland intend to convey that opinion.

6112. Is the only thing that you find fault with the estimate of the previous sewage contamination?—That is the only objection I have. I have no objection to the nitrates that Dr. Frankland finds in the water. I only object, as all chemists object, to the statement that those nitrates are due in the case of chalk water to previous sewage contamination. For instance, upon that data, if you refer to Dr. Frankland's report for August, you find he reports that the river Lea contained no sewage contamination at all, which is a manifest absurdity. Again in the case of the well at Grays which supplies the South Essex Company, that was supposed to contain 8¼ per cent. of equivalent to London sewage. That it contained nitrates that London sewage would contain, there is no doubt, but that it was sewage itself is utterly impossible.

6113. (*Sir J. Thwaites.*) As far as your present supply is concerned, drawing it from deep wells, it is quite clear that there can be no sewage contamination?—The impression abroad is that it is absolutely a mixture of sewage with our water supply.

6114. I understand your system is now so perfect and so entirely distinct from the original source of supply, namely, from the valley of the Ravensbourne, that you draw the whole of your present supply from deep wells?—The whole.

6115. Is there any place between the lift and the source of supply into which sewage can flow?—None.

6116. (*Chairman.*) Will you be kind enough to describe the mode that you adopt in order to get the water?—The greater part of our wells have the chalk very near the surface. We pass closed cylinders of iron from 70 feet to 100 feet down, so that we effectually exclude all the surface water, and we then proceed to bore or drive, as the case may be, until we obtain the quantity of water which we require.

6117. Is there no possibility of any soakage going into those chalk wells from the cultivation of the land?—It is utterly impossible. Whatever soakage there is must be that which would come in by infiltration. The whole of this chalk water has its origin in the rain falling upon a district lying very wide, and it filters through the chalk and passes down 200 or 300 feet, and rises finally out of our wells.

6118. But if the water be due to the rainfall passing through cultivated land, would it not possibly take the sewage through to the wells?—There is no doubt that the nitrates of Dr. Frankland may have their origin from that source, but at the same time they are changed from their original form of ammonia into nitrates, and that very change supposes the conversion into a harmless compound.

6119. And has that rain passing over and flowing upon the ground, and then through the chalk into the well, by the time it gets down to the bottom of the well been relieved of its impurity?—Yes; in fact it

W. R. Morris, Esq.

26 Feb. 1868.

is the great laboratory of nature. The whole body of chalk acts with precisely the same effect as is recommended by filtration through animal charcoal. Precisely the same result is arrived at, on a very large scale, as is proposed to be done by the experiments of the chemists of the present day.

6120. Have you any knowledge of the wells at the Woolwich Arsenal?—None, but their water is not so good there. I have not analysed it, but I know that we supply the arsenal with water from our wells.

6121. Then you do know the wells that supply the arsenal?—We supply the arsenal with water, I suppose, in preference to their own water which they have there.

6122. You admit that your water is some degrees harder than the river Lea, and the East London Company's water?—I should think it is.

6123. Twenty-seven, 19, and 18, are the relative figures. Do you agree with that?—I should say that that is quite correct.

6124. And the Grand Junction 19?—Yes. I may say that after five minutes boiling the waters all become equal.

6125. You mean equal to the other before it is boiled?—No; if you boil the river Lea water and the Kent water, which is chalk water, you will find them to be both of the same degree of hardness.

6126. Have you any experience of Dr. Clark's process?—I have not. We took possession of the Plumstead works, where the process had been going on for some years, but we did not carry it on. We found the whole thing so imperfect and so utterly not to be depended upon, that we were obliged to abandon it. The only instance where Dr. Clark's process was carried out on a large scale was at the Plumstead works, and I may mention that the water softened by that process seemed to have a great effect upon the lead cisterns in that district. We found in many instances that the cisterns were perfectly destroyed. That shows that you may carry the system of softening water to too great a length—that a certain amount of lime is necessary to preserve water from contamination from lead.

6127. The water supplied by your company has been used, has it not, by a very large district?—Yes.

6128. Have you any means of telling us how many gallons per head per day you supply?—About 25 gallons.

6129. Is that the gross quantity?—Yes, we have not many manufactories in our district.

6130. How would you make that quantity up; how much for domestic purposes?—I do not distinguish between the two; dividing the total quantity pumped by the number of houses, comes to about 25 gallons per head per day, and as we have very few manufactories in our district that fairly represents the quantity of water which is used per head per day.

6131. What do you allow for waste?—I cannot distinguish between use and waste. There is no saying where the one ends and where the other begins.

6132. (*Sir B. Phillips.*) What is the population of your district?—I am not prepared to say that either; we supply 35,000 houses.

6133. What is the gross quantity of water per diem that you pump?—I do not remember the exact quantity, but I have prepared a diagram showing the increase from 1840 to 1867, which I will beg leave to hand in to the Commission. (*The same was delivered in. Vide Appendix S.*)

6134. (*Chairman.*) According to this diagram in the year 1840 you supplied 120,000,000 gallons in the year?—Yes.

6135. And you now supply 2,040,000,000 gallons in a year?—Yes.

6136. And the gradual increase is shown in this diagram?—Yes.

6137. Is the part coloured dark blue in the diagram that which you derive from the river Ravensbourne?—Yes, and the light blue is derived from springs.

6138. In the years between 1855 and 1860 you had completely exhausted the Ravensbourne, had you?—Yes, at that point where the dark blue ends, and it gives the date when the river Ravensbourne was thoroughly exhausted. In fact the dark blue will show the flow of the Ravensbourne; we took it all.

6139. (*Sir J. Thwaites.*) Now are you supplying both the dark blue and the light?—Yes, we substitute well water for the Ravensbourne water.

6140. (*Chairman.*) Now you get your supply for all the district from the deep wells in the chalk, and you take nothing from the river. Is that because there was nothing left?—No, we have abandoned the Ravensbourne altogether.

6141. Can you form any opinion as to the amount of water that there is in the district from which you gather your supply?—At present we are supplying about 7,000,000 gallons a day; in round numbers we have machinery for raising 10,000,000 gallons, and our present wells will certainly supply 14,000,000 gallons, that is double our present day's consumption; and I have not the slightest doubt that if we went further down we could obtain any amount that we chose, that is to say, selecting certain portions of our district we could find a spot where we could get more water still.

6142. How deep do you go?—We vary from 200 to 250 feet. In one case we are about 500 feet down, but that is a small well.

6143. (*Col. Harness.*) Do you mean from the surface or below any fixed level?—From the surface.

6144. How much are the wells sunk generally below Ordnance datum?—The surface of the principal part of our wells is about 12 feet above Ordnance datum.

6145. (*Sir J. Thwaites.*) Have you depressed the water line by your pumping?—Not permanently.

6146. Have you watched that?—Yes; if we stop any of our wells the water immediately rises to its former height, which is about two feet above high-water mark.

6147. Is there any infiltration from the Thames?—No, some of our wells are miles from the Thames.

6148. (*Chairman.*) Have you at all taken into consideration the Thames basin as a source of supply, or has not that come within your knowledge?—No, I have never taken that question up.

6149. (*Mr. Harrison.*) Is the report which you have handed in in the nature of a monthly report made to your company by Dr. Letheby?—No; Dr. Letheby analyses twice every month our water, and makes a report; this is a special report.

6150. (*Chairman.*) Has your attention been turned to the question of constant service?—It has very much.

6151. What conclusion have you arrived at as to the benefit of that system to the population generally?—I am very favourable to a constant supply.

6152. First of all, will you state what is your supply?—Our supply is intermittent, except where it is by meter.

6153. You have reservoirs in the houses, I presume?—Yes. If we could get rid of the waste we would adopt the constant supply directly.

6154. Then the provisions of the Act of 1852 have never been put into operation in your district?—We have never had the slightest application for it.

6155. But you think that a constant supply would be a very good thing?—I do, if we could once prevent waste, or if we had power given to us to prevent it, or any mode were devised by which we could get rid of the enormous waste which is attendant upon a constant supply as carried out under the present system, we have no objection.

6156. When you say if you could get power given you to do so, have you ever considered what powers would be satisfactory for preventing waste?—I think that the power which would be required must be vested in what we may call a water police; there should be a constant inspection, which I know that the public would not bear, but unless we had power to exert that it is perfectly out of the question. I have made some experiments, and I know that people have wasted as much as 2,000 gallons a day per house for

a twelvemonth together ; and in the case of meters, we supply by meters because then we do not care how much they waste, as they have to pay for it, but they complain in several instances, especially by persons unacquainted with the system of the amount of their bills. The question is to find out how those bills arrive at such an amount. We find that they themselves with all their care cannot prevent waste, and can hardly account for it. A pipe gets broken or a watercloset is left running, and away goes a million gallons of water before you know where you are.

6157. In such a case the house would be flooded ?—It is so ; a pipe broke across a drain the other day in a large house at Blackheath, and the loss of water was enormous before the defect could be discovered.

6158. (*Sir J. Thwaites.*) Having regard to a properly arranged system of supply, pipes of sufficient strength to resist the pressure, and an efficient supervision, you are of opinion in the first place that a constant supply would produce a great saving of water, and in the second place promote the health of the inhabitants ?—I will confine myself to the saving of water. I have no doubt there would be a great saving of water, but the restrictions must be very stringent, otherwise it would completely absorb the whole of our power of supplying ; you might pour water upon the sea beach with as little effect.

6159. (*Chairman.*) You think it necessary, if I understand you aright, to have some very stringent police regulations ?—I do not say police, but something of that nature, persons armed with authority who could go into the houses and prevent waste.

6160. That is to say, in order to see that the taps and cocks and pipes are in good order ?—Yes, to see that they are kept closed.

6161. (*Col. Harness.*) Have you ascertained what the average consumption is per head where the supply is given by meter ?—It does not seem to vary. I do not perceive much difference between the supply to a private house with a meter and without it ; that is to say where things are properly regulated, the charge by meter comes to about the same sum as we should charge to the house without a meter.

6162. (*Chairman.*) Do you say that you pump 7,000,000 gallons a day ?—That was our last year's pumping, our average does not come so high as that for the whole of the years.

6163. And you could get by extra machinery 10,000,000 gallons ?—14,000,000 gallons is certainly the yield of the present wells.

6164. You said that you could get a much larger supply ; is it possible to form an idea as to what supply you could get, whether it would be double or treble that ?—I should not like to speak as to that. It ought to be, that is all I can say.

6165. (*Mr. Harrison.*) Is yours a healthy district generally ?—Yes, very.

6166. What is about your death rate ?—I do not know the death rate, but in Lewisham and Blackheath the death rate is the lowest in the whole district, and as low as in any of the metropolitan districts.

6167. Have you ever had any complaints of the effect on health of the supply of water in your district ?—No, nor any complaints at all of the water.

6168. (*Sir J. Thwaites.*) They have not reached you, I presume ?—They must reach me if there are any complaints.

6169. (*Mr. Harrison.*) Is this question of sewage contamination a new mode of estimating the quality of water ?—Yes.

6170. How long has it been introduced ?—I cannot say exactly, but it can be ascertained by reference to the Registrar General's returns ; but within the last two or three months Dr. Frankland has again changed his estimate and formed a new one. It is found, in fact, that the nitrates exist largely in rain water, that is to say, those nitrates which are supposed to be due to sewage. You have a very large per-centage of ammonia in every shower of rain that falls during a thunderstorm, and under ordinary circumstances no rainfall takes place without some amount of ammonia, which produces those nitrates.

6171. (*Chairman.*) Then your evidence goes to show that the nitrates which are found in your water are what are found in all rain water and therefore are not attributable to sewage contamination ?—Not precisely that. I do not mean to say that you will find in rain water the amount of nitrates which you will find in chalk water ; still there are nitrates in rain water, and according to Dr. Frankland's theory it ought to be sewage, and sewage is out of the question in the case of rain water ; but I have no doubt that the chalk, which is nothing but a mass of organic remains, contains in itself large quantities of nitrates due from those remains, but they are perfectly harmless. I never heard Dr. Frankland or anybody else say that there was the least detriment whatever from the use of those nitrates, and the water itself is perfectly pure from any organic matter.

6172. (*Col. Harness.*) Do you find that your wells at Deptford, when you are not pumping from them, vary in level with the state of the tide in the Thames ?—No, I do not observe any variation whatever. We have three wells at Deptford, and to give you an idea of their yield, if we stop any one well and keep the other two wells pumping, that well which we stop rises to its original level, although the wells are within 300 yards of each other, and their level is about two feet above high-water mark, and when the tide falls we do not perceive any difference.

6173. What distance are they from the Thames ?—I suppose about a mile.

6174. (*Chairman.*) I see under the head of "ammonia" that your water is ·003 and the Lea water ·006 ; therefore there is more ammonia in the Lea water than in yours ?—It varies very much. I do not place much reliance upon that. The amount is so infinitesimal when you come to calculate it out, one in 50,000,000 parts, that it is hardly appreciable.

6175. (*Mr. Prestwich.*) Will you put in your evidence that paragraph in the report of the year 1851 in which Professors Graham, Hofmann, and Miller express their opinion of the quality of chalk water ?—It is the last concluding paragraph in the report, and it is in these terms : "The water recommended "appears to approach most closely to the standard "of all that is excellent in a town supply, and "is worthy of the greatest efforts and grandest "works to procure and convey it. But the sources "are near at hand and the water is attainable without "difficulty or great expense. With such a noble "application of the chalk spring water in view as the "supply of the metropolis, it would be a desecration "to permit that water to be wasted on other uses, "and most impolitic to allow the possession of it to "pass into private hands. It is our deliberate opinion, "which we would enforce in the strongest terms, that "the much desired and most necessary improvement "in quality of the London water is associated with "these sources of supply, and will depend upon their "proper application to the uses of the public."

6176. You have increased the number of wells according to the increased demand for water, have you not ?—Yes.

6177. And as you have still a district in which the demand increases do you see a limit, by increasing the number of wells, to the power of sufficient supply for that district ?—We conjecture so ; of course it must be conjecture. Hitherto we have not made a mistake, but I do not mean to say that we might not select a spot which would be worthless, but I have no doubt that we could get an incalculable amount.

6178. Have you been successful in obtaining water in all the wells which you have sunk ?—Yes, in all the wells.

6179. At the different levels ?—Yes. We have one well where the water stands 70 feet above Trinity high-water mark.

6180. In sinking those wells you had I presume in most cases to go to a certain depth before you reached the source of supply, that is to say, you did not meet

W. R. Morris, Esq.

26 Feb. 1868.

with water at the same level or indifferently in the chalk as you proceeded?—No, we generally find a good deal of water in the chalk immediately we pierce it. It depends of course upon the situation. At Deptford we find most water at about 100 feet down.

6181. When you come upon a spring, do you usually meet with a spring of considerable force, or do you extend your well by galleries, so as to increase the source of supply?—We work both ways. We generally select a spot as near as we can upon a fault, and having found the spot we sink down, and we sometimes have obtained water immediately by boring without any further trouble whatever; an 18-inch bore-hole takes us down to it, but in some cases we have had to drive adits into the chalk, and to collect the water as we went on. We generally find that a great quantity of water comes from the bottom of the springs upwards.

6182. Is there anything to indicate that any infiltration takes place in the vicinity of the well itself?—No; nearly the whole of the water seems to rise up from the floor of the adit in which we are working, and it is drawn from a distant source where the chalk comes to the surface.

6183. Have you had the waters from the different wells analysed?—Yes, the whole of them.

6184. Do you find much difference in the composition of the water?—There is a considerable amount of difference between the wells in that respect.

6185. In the proportion of nitrates do you find them to vary?—They do vary, and they vary sometimes according to the seasons. I cannot account for it, but they do vary slightly according to the seasons; and we find that pumping a well after a few years slightly hardens it, that is to say, we get a slight increase of carbonate of lime.

6186. Is not that rather contrary to the notion of the usual action of wells, where the more you draw upon them the less mineral matter they contain?—Yes. I mention that because it is a fact which I was not prepared for when I first commenced searching for water, but so it is, that we get more carbonate of lime as years proceed; there is a slight difference, instead of softening the water gets slightly harder.

6187. How is it as to the other substances?—They remain about permanent.

6188. Has Mr. Wanklyn applied his test to the water from those wells?—I do not think he has. I have not seen any report of it if he has.

6189. (*Chairman.*) Are we to understand you distinctly to say that the reason you left the river Ravensbourne was that you had exhausted its power, there was no water left in it?—We pumped the whole that came down, and having a larger demand we sought for water in the chalk, and having discovered it, we found that it was much better water than that which we had obtained from the Ravensbourne, it pleased the public much better. It required no filtration, and the result was that we adopted the chalk water and abandoned the other.

6190. (*Mr. Harrison.*) I asked Mr. Quick a question as to the cost of pumping. Can you give us any information upon that?—No, I cannot. The cost of pumping varies so much in each establishment that we have that I can give you no data. If I were asked to give a formula to determine the cost of raising water to given heights, it could be done, but it would be a great deal of trouble, in our case particularly.

The witness withdrew.

The witness subsequently sent in a copy of the following letter:—

(Copy.)

University College,
25th February 1868.

Dear Sir,

I have the honour to report the following results of my analysis of the water supplied to me at Bromley on the 18th inst., and reported to have been drawn from a main of the Kent Waterworks.

The water contained, dissolved in 100,000 parts—

Solid residue	32·7
Nitrogen, as Nitrates and Nitrites	·403
Organic Carbon	·064
„ Nitrogen	·044
Ammonia, a trace not above	·002

Total hardness of the water is 21·7 degrees, and the permanent hardness 4·8 degrees.

I remain, yours faithfully,
(Signed) A. W. Williamson.

R. Latter, Esq.

Adjourned to to-morrow at 12 o'clock.

Thursday, 27th February 1868.

Present:

His Grace THE DUKE OF RICHMOND in the Chair.

Sir John Thwaites.
Alderman Sir Benjamin Phillips.
Colonel Harness, C.B.
Thomas Elliot Harrison, Esq.
Joseph Prestwich, Esq.

Dr. Edward Frankland, F.R.S., examined.

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

6191. (*Chairman.*) What position do you hold?—I am a Fellow of the Royal Society, Corresponding Member of the Imperial Institute of France, and Professor of Chemistry in the Royal Institution and in the Royal School of Mines.

6192. You have had great experience, have you not, with regard to the chemistry of potable waters?—During the last three years I have been engaged in examining monthly the waters supplied to London for the Registrar General's Report; and consequently I have been brought a good deal into contact with those waters as a chemist, and during that time, and I may say for the last 20 years, I have been also more or less engaged in the same kind of work.

6193. You have been engaged recently, have you not, in connexion with Dr. Odling in analysing samples of waters collected in North Wales and Cumberland and Westmoreland?—I have.

6194. Were those the samples of water which were handed to you by Mr. Pole?—They were.

6195. You are probably aware that he went down at the instance of this Commission to the lake districts and to Wales for the purpose of collecting samples in order to have them analysed by yourself and by Dr. Odling?—Yes, and I received at the same time Mr. Pole's reports upon the collection of those samples in the two districts.

6196. (*Sir J. Thwaites.*) Have you seen the evidence which Mr. Wanklyn gave before this Commission?—I have.

6197. Have you observed that in that evidence he lays down some fresh principles or analytical arrangements, more especially with regard to water?—Yes.

6198. He does not agree with you in your mode of separating the elements or describing them, and he states in that evidence that Dr. Frankland is now pretty

much of the same opinion with himself as to the proper mode of analysing the water. Before you go into your general evidence, will you have the goodness to state whether you are agreed in your mode of examining water, or whether you are still at issue upon that point?—We are still I think entirely at issue upon that point, as we always were; Mr. Wanklyn and Mr. Chapman proposed early last year a new mode of examining waters with regard to the organic nitrogen which they contain, founded upon the chemical reaction between permanganate of potash and albumen. The process did not on *à priori* grounds inspire much confidence in the minds of chemists as to its service when applied to waters, because we not only do not know that water contains any albumen whatever, but the nitrogenous organic principles contained in water are so utterly unknown to chemists, that any process founded on a reaction upon one particular species of nitrogenous organic matter could not with confidence be applied to potable waters containing unknown principles of that kind.

6199. Then we are to understand that you still adhere to your mode of examining waters, and that you are not, as alleged by Mr. Wanklyn, of opinion that his process is the proper one to ascertain the constituent elements of water?— Certainly not. I never expressed any such opinion. When he stated that in his evidence, he must have mistaken the purport of some conversation that we had upon the subject. But perhaps I may be allowed to state that at the time his process was proposed, my colleague, Dr. Odling, and myself thought that we should not be justified in ignoring it, therefore we have submitted every sample of water collected from the two districts for this Commission to Mr. Wanklyn's process, and the results of those analyses are contained, with our own results, in our report which has been already presented to the Commission. That result will be found in each table under the head of "ammonia evolved on boiling with permanganate of potash." At page 4 of the report under the head of "other determinations and estimations," you will find "ammonia ob- "tained by distilling 100,000 parts of each water with "permanganate of potash." That is the determination of Mr. Wanklyn and Mr. Chapman, and we comment upon its results, in relation to the process which we adopt in these analyses, in another part of the report, or rather I comment upon it; but I may mention that my colleague is perfectly agreed in this comment. At page 12 there is this paragraph:—"In addition to the organic "nitrogen as thus determined by direct analysis, we "have also estimated the amount of ammonia which "is evolved from the waters by prolonged ebullition "with a strongly alkaline solution of permanganate of "potash, the ammonia previously existing in the "water being first expelled by ebullition with car- "bonate of soda. This method has been recently "proposed by Messrs. Wanklyn and Chapman as a "means of determining the organic nitrogen in "waters. In our hands this process has yielded "somewhat irregular results. As a rule, which is, "however, by no means without exceptions, the "organic nitrogen so inferred is considerably less "than that obtained by direct analysis, and this is "markedly the case with those waters which contain "a comparatively large amount of organic nitrogen; "thus, the flood water of Troutbeck (Greta) gave us "by analysis ·068 part of organic nitrogen, whilst the "same water when boiled with alkaline perman- "ganate gave only ·016 part" (or only about one-fourth); "whilst, therefore, this process is valuable "as a ready qualitative method of ascertaining the "presence of organic nitrogen in waters, we do not "think that in its present form it can be relied upon "for the determination of the actual amount of this "element." I may mention also that since this report was written I have had further opportunity of testing the permanganate of potash process with several kinds of organic matter of known composition, in which a certain amount of nitrogen is known to exist, and in every case it has signally failed to evolve even a considerable proportion of this nitrogen in the shape of ammonia.

6200. (*Chairman.*) We have now before us your report upon the waters after having analysed them, in which you seem to have gone very fully into the subject. Is there anything which you would wish to add to the report?—Your Grace will see that there is a special part of this report which has been written by myself, and in which I endeavoured to embody that which at the time occurred to me to say respecting the analytical results, and their bearing upon the question before the Commission. At page 6 you will find "additional observations by Dr. Frankland."

6201. Could you give us briefly what is the result of your examination of the waters?—The result of the examination of the waters from both districts is, that with the exclusion of a few samples which are mentioned particularly in our report, the waters from both districts are very well calculated for the supply of a large community like that of the metropolis.

6202. Would there be any effect produced upon the waters by storing them in large quantities in reservoirs?—So far as my experience goes in the storage of waters the quality appears to be greatly improved by that storage, and therefore I should expect that in those districts where there are no large lakes to be experimented on at present, the quality of the water as now revealed by analysis would be improved if stored in large reservoirs.

6203. Would peat have any effect on those waters?—Peaty matter is probably contained to a greater or less extent in all those waters, and probably in every water that ordinarily comes before us. Almost all potable waters appear to contain a minute quantity, at all events, but the proportion of peaty matter in soft waters is usually considerably greater than in harder waters. The proportion of peaty matter in some of the water, both in the Cumberland and in the Welsh districts, in some few of the samples which are particularly mentioned in our report, is large—in fact too large to admit of their being used for a water supply in that condition. For instance, in the case of the Trout Beck (Greta), in flood, that sample contained too much peaty matter to be admissible into a town; and the Mosedale Beck, in flood, is another example where too much peat is contained to render the water a desirable one. But by storage in large reservoirs much of that peaty matter would, in all probability, be precipatated before the water would be drawn off from the reservoir.

6204. But would not all the supplies from both those districts be liable at some period of the year to great quantities of flood water?—I presume they would, if it should be found necessary to collect all the flood water and make use of it; but there are contrivances which I have seen in use at the Manchester Waterworks, for allowing the flood water, by shooting over a slot in a conduit, to escape from the reservoirs used for supply, or, at all events, those used for immediate supply.

6205. What is the case; is it not that floods in those districts take place in the course of half a dozen hours?—Yes.

6206. And the water remains in flood for 24 hours sometimes, or more?—Yes.

6207. Then all that water would contain, would it not, a great quantity of peaty matter?—In some cases it would, but the conduits of which I have spoken are self-acting; they do not require anyone to be present to shut off the flood water; the flood water shuts itself off. The moment the volume of the stream exceeds a certain maximum the flood water jumps over the slot through which it had previously been running.

6208. (*Sir J. Thwaites.*) Is there any process by which the discolouring matter can be removed from the water other than by precipitation?—There is a very excellent process for its removal which could also be carried out upon a large scale, and at no great expense, that is, filtration through animal charcoal, which effectually removes it.

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

6209. Is there anything in the idea of the stain in the water caused either by peat or any other coloring substance, so that it is difficult to remove it afterwards, either by filtration or any other process?—The ordinary process of sand filtration will not remove much of the colouring matter, but filtration through animal charcoal removes the whole of it. The colouring matter, I may mention, constitutes apparently only a small part of the organic portion of the peaty substance that gets into the water.

6210. (*Chairman.*) Water may be very much coloured after flood and still be very wholesome to drink, may it not?—Yes, certainly; and if we are to take as examples the kind of water which would probably come from large reservoirs in the Welsh district and in the Cumberland district, that water would contain a less amount of peaty matter than is frequently contained in the Thames and river Lea water at the present time.

6211. Are you of opinion that the samples taken by Mr. Pole are sufficient to give us a very perfect idea of the quality of the water in both those districts?—I think they are. The samples were taken under considerably different circumstances in the various cases, sometimes in flood, and from the same streams again in moderate weather and good weather, so that on the whole I think these analyses give a very good idea indeed of the quality of the water which would be obtained from both districts; but inasmuch as, in the Welsh district, we have no lake in Mr. Bateman's gathering grounds, the evidence there is by no means so conclusive as it is in the case of the Cumberland and Westmoreland district.

6212. Would you explain why that is?—Because we have no means of judging of the effect of storage. However, the water of the Bala lake, which is just outside Mr. Bateman's district, may probably be considered as affording an example of the kind of water which would be obtained in Mr. Bateman's large reservoirs.

6213. Did you detect any effect upon the water from mineral workings?—With regard to turbidity we did in several cases. Some of the samples collected by Mr. Pole were turbid at the time of collection, and they retained their turbidity for some weeks afterwards. All those samples which flowed from mineral workings, or were contaminated by water from mineral workings, were specially examined for noxious mineral substances, and we found in either two or three cases the merest trace of lead; but in all other cases no metallic noxious substance of any kind was present.

6214. Was that with reference to water from the lake district, or from the Welsh district, do you recollect?—I think it was in samples from the lake district exclusively that that trace of lead was found. But I may mention that the trace was so utterly insignificant that it was only just capable of being revealed by the most delicate chemical processes, and the notion that it might be hurtful when mixed with the rest of the water, or even hurtful if that water alone were drunk, is quite out of the question.

6215. You have also had great experience, have you not, with regard to the waters of the metropolis?—For the past three years I have had my attention very specially directed to those waters.

6216. Could you state first of all whether the waters which are now supplied to the metropolis are hard or soft waters?—They are what I should call hard waters, having from 14·4 up to 28·8 degrees of hardness. But I must mention that there are two kinds of degrees of hardness. These I have just quoted are the degrees of hardness mentioned in the reports to the Registrar General, and these degrees are only seven-tenths of the value of the degrees that were proposed by Dr. Clark, of Aberdeen.

6217. What would be the degrees of hardness of the water from the Welsh district, as proposed to be supplied by Mr. Bateman?—The Welsh waters, exclusive of Bala lake, would be from 3 degrees the maximum to ·7° as the minimum, and these degrees, as I before stated, are each of the value of seven-tenths of Dr. Clark's degrees.

6218. (*Sir J. Thwaites.*) Does that process of examination run through all your reports?—Through the whole of them; it is a form of expression in this report, and in all the reports to the Registrar General.

6219. That applies also to the lakes as well as the London waters?—Yes, to the lakes, to the London waters, and to the Welsh waters, and I may say also to the French waters.

6220. (*Mr. Prestwich.*) Would you be able to give us also the degrees as used by the other witnesses?—Yes, certainly, there is nothing so easy. It is only necessary to multiply by ·7.

6221. (*Sir J. Thwaites.*) It is very important that we should upon your testimony have an accurate statement of the degrees of hardness of the London waters, and of the degrees of hardness of the Welsh and the Lake waters, and that we should keep to the same language as other chemists, namely, the degrees applied to the gallon, as by Dr. Clark, and not to the litre?—The degree of hardness upon Dr. Clark's scale of the Welsh water, exclusive of Bala lake, is 2·1 as the maximum, and the minimum is ·5. The hardness of the Cumberland water (exclusive of the Lower Lowther and Dacre Beck) varies from 2 degrees to ·5. The hardness of the London water varies from 10·1 degrees to 20·2.

6222. (*Chairman.*) What does your experience tell you is the effect of the quality of the present supply in London upon the health of the population generally?—I cannot of course trace any direct connexion between the present supply and the health of the metropolis; but I consider that water contaminated with sewage contains that which is noxious to human health. There is no process practicable upon a large scale by which that noxious material can be removed from water once so contaminated, and therefore I am of opinion that water which has once been contaminated by sewage or manure matter is thenceforth unsuitable for domestic use.

6223. That is a proposition; but is there that sewage contamination in the London water?—There is undoubtedly that in the London water, which is self-evident from the circumstance that sewage flows into the Thames and the Lea. It is not so self-evident in the case of the chalk water supplied by the Kent Water Company, but chemical analysis reveals that it is there also present.

6224. Are we to understand that you are of opinion that this noxious matter exists in the water from analysis, or from knowing that sewage runs into the river from whence the companies draw their supply?—From both circumstances.

6225. Take the analysis first. What leads you to believe that there is that amount of sewage matter in the water which would be detrimental to health?—I find on analysis, as is shown in the table at page 17 of our report, that there is present in the waters delivered into London the following quantities of material, which may be regarded as the skeleton of the sewage which has been previously poured into the water; namely, of nitrogen, in the form of nitrates and nitrites, a mean quantity of ·192 part in 100,000 parts of water, that is, in the Thames water; in the river Lea water, as delivered by the New River Company, ·221 part in 100,000 parts; in the water delivered by the East London Company, which is also river Lea water, ·132 part; and in the chalk water delivered by the Kent Company, ·365 part in 100,000 parts. This skeleton, as I have called it, of previous sewage corresponds to the following quantities of average filtered London sewage, namely, in the Thames water to 1,751 parts of sewage in 100,000 parts of water; in the river Lea water, delivered by the New River Company, to 2,013 parts of such sewage; in the river Lea water, delivered by the East London Company, to 1,077 parts of such sewage; and in the chalk water delivered by the Kent Company, to 3,393 parts of such sewage. I must mention, however, that this chemical record is defective, especially in the summer months. It is defec-

tive in one direction, namely, that it gives the minimum amount of sewage only, with which the water has been contaminated; because in rivers we have vegetation in a state of activity during the spring and summer months, and also to some extent in autumn, and those aquatic vegetables remove this skeleton of the sewage to a greater or less extent from the water.

6226. You state that you have come to the conclusion that sewage has been the cause of the contamination of this water, because you find a skeleton there in the form of nitrates and nitrites?—Yes, and also of ammonia, which I think I omitted to mention, but that is a very insignificant part of the skeleton.

6227. Is it possible that those nitrates and nitrites could be present in the water without its having been contaminated by sewage? Could they be produced by some other cause than that of sewage?—They could be caused by manure thrown into the water, and by manure applied to the land.

6228. But are they attributable to nothing else?—To nothing else, I believe.

6229. With regard to the chalk water delivered by the Kent Company, you state that the mean is ·365 of nitrates and nitrites, which represent in the other column an estimated previous sewage contamination amounting to 3,393; that water we understand is taken from wells which are some 200 feet below the surface?—It is, I believe.

6230. Would the sewage get down that depth?—The skeleton of the sewage would get down that depth, and even might get down much lower than that. Nearly the whole of that water is the drainage from cultivated land, and that which is not the drainage from cultivated land is the drainage from pasture land; and according to the analyses of Professor Way of drainage waters from land, those waters contain the following quantities of previous sewage contamination in 100,000 parts. The drainage water from manured arable land contains between 54,490 parts of previous sewage contamination as the maximum, and 7,040 parts as the minimum, the average being 20,370 parts of previous sewage contamination in 100,000 parts. From unmanured pasture land the maximum is 2,100 parts of previous sewage contamination in 100,000, and the minimum 180 parts, giving an average of 830 parts.

6231. How do you account for those nitrates and nitrites not being present in the waters which were collected in those two districts of Wales and Cumberland?—Because there is no such pasture land as that which was experimented upon in the case of Professor Way's experiments. This is water which has percolated through the pasture land and made its escape from drains; whereas the water that was collected for analysis for this Commission was principally, I believe, surface drainage, water that flowed rapidly over the surface and made its way very rapidly into the stream. None of the land, or very little of the land, is there systematically drained; but there are cases, especially in the Welsh district, where this previous sewage contamination is actually indicated by analysis, as will be seen by referring to the report, it occurs where cultivated land exists on the sides of the streams, and so far as I can gather from Mr. Pole's report, such land does occasionally exist there.

6232. It would be pasture nearly the whole of it, would it not?—It would be sparsely pastured by sheep, I presume, and cattle. The minimum in this unmanured pasture land, according to Professor Way, is 180 parts, and we have a larger amount than that in some of the Welsh samples.

6233. (*Sir J. Thwaites.*) Before leaving that part of the examination with regard to the Kent water, we had some evidence yesterday to the effect that you must have been mistaken in finding traces of sewage in those chalk wells, the water being taken at a depth of 250 feet in the chalk, and the upper part of the wells themselves being lined; therefore the water must have filtered through the chalk, and there could be no trace of the skeleton of sewage. Is it your opinion that the skeleton of sewage as you describe it will find its way down to a depth of 250 feet, and that after filtration through gravel, and ultimately through the chalk, its presence will still be detected?—There cannot be a doubt about it, that this skeleton of which I speak, but which is a very different thing from the sewage itself, is present. I have never stated that the water which has filtered through the chalk in this way contains unaltered sewage; it is this inorganic skeleton of sewage that I find in water so filtered.

6234. Is it prejudicial to health?—It is not in a moderate quantity, such a quantity, for instance, as is contained in this chalk water of the Kent Company.

6235. (*Chairman.*) With regard to the Kent water, the mean of the nitrates and nitrites according to the figures which you have just given us is ·365, and that amount in water in your opinion would not render it injurious to health?—That amount of nitrates I should say would have no deleterious effect upon health.

6236. It is scarcely necessary to say that in the case of the water delivered by the East London Company, which has ·132, the water of the River Lea Company, which has ·221, and the Thames water delivered by the Chelsea and Grand Junction and other companies, which has ·192, none of those four waters as at present supplied to London could have an injurious effect upon the health of the metropolis, in consequence of the presence of those nitrates which you say are the skeletons of previous sewage contamination?—Certainly not. Those nitrates would not in any case, I believe, be in the least prejudicial to health; but they reveal the fact that those waters have been previously contaminated with sewage, and, as I have already stated, there is no method which, with certainty, can be applied to water by which the noxious qualities of sewage can be effectually removed from it.

6237. But in all those four waters, as I understand you to say, after having had them analysed, you find the presence of those nitrates and nitrites, which shows that the waters had been in previous contamination with sewage?—Yes.

6238. But although they are in that state, you state, do you not, that there is nothing in them that could be injurious to health, and therefore the water is a wholesome water to drink?—I did not intend my statement to go so far as that. I meant only with reference to those nitrates in themselves, that the skeleton of the former sewage which is represented by nitrates and nitrites is not injurious to health; but we have no guarantee that other portions of that sewage may not have escaped the process of filtration through the chalk, and filtration through the land or over the land, and may be present in that water. Those substances are in too minute a quantity to be capable of detection by chemical analysis.

6239. Then your answer would apply as far as the nitrates would enable you to judge?—As far as the nitrates themselves are concerned that quantity of sewage matter which they represent is in an innocuous form in the water.

6240. The presence of what other elements would lead you to a conclusion upon the quality of water as regards health?—In the first place when water is once contaminated with sewage, there is no process to which it is afterwards subjected which will effectually remove all that sewage contamination from the water. Filtration will not do it in certain cases, at all events. I have proved that the excrements of cholera patients cannot be filtered out of water; that after a degree of filtration which I believe is never attained by the water companies, and rarely attained perhaps by the passage over soils in irrigation, this water still remains opalescent, from the rice-water evacuation with which it has been mixed. The degree of danger which still remains in waters from different sources varies obviously according to the amount of filtration that the water undergoes. I would much rather drink the chalk water of the Kent Company, even if it had been contaminated to four times the extent of the Thames water, than I would drink the Thames water, because if I could have the assurance that none of that sewage

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

or manure water had found its way into the wells through fissures in the chalk, the chalk water having passed through say 100 feet of chalk, would be very much better filtered than any water which finds its way to the Thames.

6241. (*Sir J. Thwaites.*) When you speak of the difficulty of removing the effects of sewage contamination, does that difficulty apply to that which is held in mechanical suspension, or to that which is held in solution?—To that which is held in mechanical suspension. I believe that the noxious part in sewage is that which is held in mechanical suspension, not that held in solution.

6242. Will no system of filtration remove it?—I would not say that it is impossible to remove it, but no system of filtration will secure its removal. There are only two processes by which it can be effectually removed; the one is by boiling for a long time, and the other is by distillation; and therefore it is that I say that, inasmuch as those two processes are impracticable on a large scale, in my opinion water that has once been contaminated by sewage ought not afterwards to be used for domestic purposes.

6243. (*Chairman.*) I see in your report to the Registrar General, dated the 31st of January in this year, "The waters delivered in London during the "latter part of January by the Chelsea, and especially "by the Southwark and Lambeth companies, were "in such a muddy condition as to render them totally "unfit for domestic use. The Thames has overflowed "its banks above the point at which the water supply "is withdrawn, and by washing the surfaces of cultivated fields, and mingling with the contents of "stagnant ditches and ponds, has become contaminated to an intolerable degree. Those companies "which, like the West Middlesex and Grand Junction, possess ample and efficient filtering apparatus, "were enabled so far to cope with the difficulty as to "send out their supply free from suspended matters." Towards the end of your report you state, "The West "Middlesex Company's water, though well filtered "and perfectly transparent, had been thus contaminated to an extent which would be produced by the "admixture of one-third of a gallon of average "filtered London sewage with each ten gallons of "the water. The river Lea also exhibits a very "high previous sewage contamination." Do you imagine that if those companies had proper filtering apparatus the water would have been supplied to the metropolis in a wholesome state?—It has been proved that water which is perfectly transparent to the eye still contains germs of animalculæ which afterwards develope in that water, and my remarks apply there to the appearance of the waters to the eye. The appearance of the other samples of water that were delivered by the Southwark Company on the 21st of January last, and the Lambeth Company, and to some extent by the Chelsea Company, may be judged of by this specimen of the Lambeth water which was drawn for analysis from the main on the 21st of last month (*producing a specimen*), and it is not much better this month.

6244. Then are we to understand you to say that no amount of filtration would render those waters fitted for the supply of the metropolis?—As I have stated, no process of filtration that has hitherto been devised will remove choleraic dejections from water; and inasmuch as it is generally believed that the noxious matter of sewage exists there in the form of minute germs which are probably smaller than blood globules, I do not believe that even filtration through a considerable stratum of chalk could be relied upon to free the water perfectly from such germs.

6245. Do you believe that the Thames basin could supply the metropolis with good and proper water if the supply were taken higher up the river than the point at which it is taken now?—At the present moment I have no means of judging of that satisfactorily, because there is no analysis of the sources of the Thames that I am aware of, to enable me to form an opinion.

6246. Do I correctly gather from your evidence that you think that no water that had passed over or through any cultivated district would be proper for the supply of the metropolis or other large towns?—I do think that that water is not safe for human consumption afterwards.

6247. That being your idea, would not it follow that no water could be supplied to the metropolis in a wholesome state from the Thames basin, because the whole of the Thames basin is as we all know very considerably cultivated?—Yes, I think it is very likely that that would be so; and inasmuch as the chalk water from shallow chalk wells exhibits this previous sewage contamination, I should infer that the springs feeding the Thames would also exhibit that contamination; but that does not necessarily follow, because it is stated that the deep chalk wells furnish a water free from nitrates and ammonia, or very nearly so, and consequently they are not so contaminated.

6248. Do you think then that there is a point below which the sewage matter would not get down?—At all events there is a point apparently below which the skeleton of the sewage no longer finds its way, it is either consumed by some living organisms and converted into other forms of matter, or it is absorbed by the strata themselves through which it passes. I have not myself analysed the waters of the deep chalk wells, but Mr. Dugald Campbell has done so, and he states that they are free from nitrates.

6249. The sewage which you allude to I presume would be the manure which the land would be subject to where a great quantity of stock was kept upon the land?—Yes, the drainage from such land I should consider unsuitable for a water supply.

6250. Would not that rather lead to the conclusion that you could get no water except in those very deep chalk wells, unless from a district where there is little or no population?—Yes, it would certainly lead to that conclusion.

6251. If I understood you aright yours was merely a general proposition, that if water was contaminated with sewage it would be unwholesome for domestic use for the purposes of the inhabitants of the metropolis, inasmuch as you find in these various waters the nitrates which you deseribe as skeletons of sewage?—Yes, because there are no processes by which the sewage contamination can be effectually removed on a large scale, my opinion is founded upon that.

6252. That is the conclusion that you have arrived at from the general state of things with regard to the waters; but is it a fact that the health of the metropolis is in any degree injured, or that there is any amount of disease caused by the water?—I think there have been some very notable instances of that kind. In the cholera outbreak in the year 1849, and again in 1854, we had evidence from Dr. Farr in the reports of the Registrar General that great mortality prevailed in those districts which were supplied with Thames water that was largely contaminated with sewage.

6253. You are probably of opinion that the use of water largely contaminated with sewage in districts which were very closely populated and where there was an absence of air and cleanliness, would tend to produce cholera; but speaking now of the water that is generally supplied throughout London, not in any particular district where the water is known to be contaminated with sewage, either by soakage going into some particular well or otherwise, do you trace any disease consequent upon that?—I have gone carefully through the evidence with regard to the connexion between the outbreak of cholera in the East of London on the recent visitation and the water supplied by the East London Company, and I have come to the conclusion that there was a direct connexion between the water supply and the outbreak of the disease in the eastern portion of London.

6254. In the East London water the mean of nitrates is according to your table ·132, is it not?—

Yes, that is for the whole of last year; it has been wonderfully improved since that outbreak occurred.

6255. And the mean in the water of the New River Company being ·221, and in the Chelsea Company ·192, there was consequently in those waters of the New River Company and the Thames water a greater amount of the skeleton of sewage than in the East London water?—There was, taking the whole of last year.

6256. But in those districts supplied by the New River, and the West Middlesex, and the Grand Junction companies, there was less cholera, was it not?—Yes, but this analysis did not extend back to that time.

6257. But if that is so, would not it seem probable that the cholera was attributable to other causes than the water, inasmuch as according to this analysis the water in those two districts supplied by the New River Company, and by the Chelsea, West Middlesex, Southwark, and Grand Junction companies, is a worse water than what you describe as having caused the cholera?—At the time of the cholera outbreak, the water delivered by the East London Company, as determined by chemical analysis, was rather worse than any other water delivered in London, but not very remarkably worse. Before the cholera outbreak of 1866 the water delivered by the East London Company from the Old Ford reservoir had never been analysed by me. The monthly sample of the East London Company's water had, prior to August 1866, always been taken in Shoreditch, which is supplied from Lea Bridge.

6258. Then if the deduction which you draw is a correct one, that it was attributable to the water, the other districts ought to have been equally visited?—I think not, because there was a special reason why this East London water should have been particularly contaminated at that time. There exist two open reservoirs near the supply reservoir at Old Ford, and those open reservoirs were filled by filtration through a bank of gravel with water from the river Lea. It has been proved in evidence before Captain Tyler that this water in the uncovered reservoirs, which was ostensibly kept there for emergency in case of fire, was regularly, or I should rather say irregularly, according to the demand, mixed with the filtered water which was sent out from Old Ford; and it was so mixed a few days before the outbreak of cholera in the East of London. There was a sluice which permitted of this water in the uncovered reservoir being allowed to flow uninterruptedly into the covered reservoir; again this covered reservoir at Old Ford is situated in a porous soil, or one-half of it at least is porous, and very much saturated with sewage. And it was also proved in that inquiry conducted by Captain Tyler that a good deal of soakage of foul water from the surrounding soil made its way into this covered reservoir, from which the best quality of water distributed from Old Ford was sent; so that there was a special cause of contamination in that water, over and above the general contamination which was common to the whole river supply of London.

6259. You have spoken as to the properties of the London water with regard to health; what is your opinion as to the effect upon health as between hard water and soft water?—My opinion is that there is no difference.

6260. You mean, of course, provided it is free from sewage contamination?—Yes.

6261. With regard to their use in manufactures, what is your opinion?—There is a great advantage in the use of soft water.

6262. You are acquainted, I presume, with Dr. Clarke's process for softening water?—I am.

6263. What is your opinion of it?—It is a beautiful process, and comparatively a very simple process, but I believe that it could never be carried out for the softening of such vast volumes of water as are required for the supply of London.

6264. The Commission have had laid before them a piece of lead (*handing the same to the witness*), and it has been stated that its appearance is the effect of Dr. Clarke's process; will you state what your opinion is with regard to it?—I should think that this effect has been produced upon the lead by some very special circumstance. It appears to me that there has been a piece of mortar, or a piece of lime, or something of that kind, upon each place where the lead is eaten into. It is obviously not uniformly attacked, and it is well known that lime or mortar placed upon lead will induce a rapid corrosion of the lead upon the place where it falls. And the cause of this is quite evident; the lime abstracts from the water the carbonic acid, which is usually the protecting material, which most effectually prevents the London water, for instance, from acting upon lead; but if this carbonic acid is removed by the lime or the mortar, then the oxygen dissolved in the water, and which is not so removed by the lime, affects the lead, and a rapid corrosion at that point takes place.

6265. What effect has soft water upon lead?—Soft water is much more liable to act upon lead than hard water, but we have many cases in those waters which have been examined by my colleague and myself for the Commission, of very soft water not acting in the least upon lead, even upon bright lead, so that there is no necessary connexion between the softness and the action upon the lead.

6266. Does the London water, which we call a hard water, become soft by boiling?—If it be boiled for half-an-hour it is softened very considerably.

6267. What would the difference be between two given portions of water, taking either the Lake water or the Welsh water, and the London water, and boiling them both the same period, what would be their condition at the end of that time, would they retain their proportionate degrees of hardness, or would they both be at the expiration of the time equally soft?—Not quite equally soft. The Welsh and Cumberland waters would be very much in the same condition at the end of the boiling as they were at the beginning; the London waters would be reduced to about four or five degrees of hardness by that circumstance, and would therefore still be harder than the Welsh and Cumberland waters, but not much harder.

6268. Then would boiling the London water cause it to lose from nine to ten degrees of its hardness?—It would.

6269. Have you given your attention at all to the advisability of a constant supply, or do you confine yourself only to chemical matters?—I have thought a great deal about it, and I have had experience of both systems of supply for a considerable length of time. I was for more than six years a resident in Manchester, and was supplied there upon the constant system with very soft water, and I have since resided 10 years in London, and have been supplied upon the intermittent system with hard water; and although I cannot complain of the amount of water which is now delivered into my cisterns in London, still there are times when we are short of water, and have to apply to the turncock to grant us a special supply, and I must say that this is always done with the greatest readiness when such an application is made. But with regard to the deterioration of the water by storage in cisterns and in tanks, I think that too strong an opinion can scarcely be expressed. In my own house, when I first went to it, I found that the waste pipe from the cistern which was to supply us with water was not furnished with a trap at all, but that there was free communication between the sewer and the interior of my house through this pipe, and sewer gases were brought just upon the surface of the water in the cistern, and I believe that is the condition of most of the houses around me at Haverstock Hill. I had this pipe trapped in the ordinary manner by bending up the end of it so as to form a loop in which the water lodged; but inasmuch as the companies will not allow, if they know it, the water to rise in the cistern so that an overflow should take place through the waste pipe, this water which seals the waste pipe gradually evaporates, and in the course of two or three months there is again the same free

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

communication between the drain and the interior of the house, and on many occasions I have found this to be the condition of things. At the present moment I am having the waste pipe removed, and having a self-acting valve placed which is to act by means of a floating ball to replace the waste pipe, so that there can be no further contamination of that kind.

6270. (*Sir J. Thwaites.*) Does water absorb the gases which are generated in the sewers?—Water will absorb the gases readily. I do not, however, attach very much importance to the mere absorption of gases; but those gases from sewers in all probability contain also floating in them organic germs, and it is those which, when conveyed into the water in this way, are productive of mischief afterwards.

6271. (*Mr. Prestwich.*) The result of your analysis shows, does it not, that those Welsh and Cumberland waters contain but a very small quantity of solid impurities?—A very small quantity.

6272. Those samples of water were taken during the months of May and June. Have you any reason to believe that those solid impurities would vary according to the season of the year?—I think they probably would, but within comparatively narrow limits. I think if you refer to the analyses made by Mr. Way of those waters that were taken in the winter months, you will find that the total solid impurity is somewhat in excess of that which is given in our analyses, markedly in excess, but still the additional quantity is not very great.

6273. In your experience with regard to the Loch Katrine water, have you found there any variation from month to month throughout the year?—I have only examined the Loch Katrine water once, and that was a sample taken, I think, in the month of February last year.

6274. Of what do the solid impurities in the waters of the two districts of Wales and Cumberland consist?—They consist, in the first place, of certain mineral matters, of which the following are the principal, namely, lime, magnesia, potash, soda, sulphuric acid, silica, chlorine, small quantities of nitrates and nitrites, and small quantities of ammonia; and, secondly, organic substances.

6275. With regard merely to the mineral contents, what would be the proportion of carbonate of lime?—The proportion of carbonate of lime is with very few exceptions remarkably low. In our analyses we get the results in parts of lime, not of carbonate of lime; but if you multiply those results by $1\frac{3}{4}$ you get very nearly the quantity of carbonate of lime—thus the Severn water is represented as containing ·417 of lime, which would be about ·745 of carbonate of lime in 100,000 parts of water.

6276. It shows, therefore, a permanent difference between those waters and the London waters of some 10 or 15 degrees of hardness?—It does.

6277. For drinking water you say you attach no importance to that difference of degree of hardness?—Not as regards its effect upon health, but I attach great importance to it in the use of water for cleansing purposes.

6278. Apart from the degree of hardness, in searching for water for the supply of a town what should you be most careful in avoiding, having reference to the health of the population?—In avoiding a water which had ever been contaminated with sewage or manure matter.

6279. You stated, did you not, just now that the previous contamination, so far as it had ended in the formation of nitrates and nitrites, was of no importance?—That portion of the sewage which has been converted into nitrates and nitrites is of no importance.

6280. Therefore generally that might be left out of the question also?—Yes, so far as that itself is concerned.

6281. Apart from those two elements of consideration, what should you consider the substance to avoid?—In any water nitrogenous organic matter would be a substance to avoid.

6282. It appears in the analysis which you have given of the water from Wales and from Cumberland, as compared with the London waters, that the organic nitrogen is the lowest in the latter; that is a substance, I presume, which it is of chief importance to avoid in water?—Yes, it is.

6283. You say in your table that the mean of organic nitrogen in the water delivered by the Chelsea Waterworks is ·011?—Yes.

6284. And the mean in the water of the River Lea Company is ·002?—Yes.

6285. And the chalk water from the Kent Company is as low as ·001?—Yes.

6286. I see further that you give the mean of Loch Katrine water as ·008?—Yes.

6287. And in the water supplied to Manchester it is ·026?—Yes.

6288. And the water supplied to Lancaster is the only one which reaches the low quantity of the Kent Company, both being ·001?—Yes.

6289. And it appears that those waters from the Welsh district show means of ·006 and of ·004, whilst Bala lake gives ·001. Therefore it appears by this analysis that there is no superiority in the waters from the Welsh and Cumberland districts over the London waters, as far as regards the presence of organic nitrogen?—As far as regards merely the presence of organic nitrogen there is not, as I have in fact stated in my report, any ground for selecting the one in preference to the other; but if we take into consideration the nature of the organic substance of which this organic nitrogen forms a part, there is a considerable difference I find between the organic nitrogen in the waters at present supplied to London and the organic nitrogen in the waters of the two proposed districts, and this difference lies in the proportion between the organic carbon and the organic nitrogen in the three cases. In the case of the two proposed districts, the proportion of organic carbon and organic nitrogen, that is, of nitrogen to carbon, varies in the strongly peaty waters between 1 to 13 as the maximum, and as the minimum 1 to 95; that is to say, in the waters which are distinctly peaty waters in the two districts of Cumberland and Wales, which contain a considerable proportion of organic nitrogen, the proportions vary between those limits, namely, 1 to 13 as the maximum, and 1 to 95 as the minimum. I have found that the relation between the nitrogen and the carbon in the organic matter present in sewage varies between 1 to 3 as the maximum, and 1 to 5 as the minimum. Therefore, there is a larger proportion of nitrogen in the organic nitrogenous matters present in sewage than there is in the organic nitrogenous matters present in the peaty substances with which water is contaminated. The proportion existing between nitrogen and carbon in some of the London waters I have calculated out. In the sample upon the table which came from the Lambeth Waterworks, the proportion between nitrogen and carbon there is 1 to 8·8. In the Chelsea Company's water, which was in a very bad condition also last month, the proportion was 1 to 6·08, and in the Southwark Company's water the proportion was 1 to 8. I infer consequently from those numbers that the waters delivered by the Chelsea Company, the Southwark Company, and the Lambeth Company, on the 21st of last month, were contaminated with unoxydised sewage.

6290. Have you any mode by which you can distinguish the difference between nitrogen derived from animal substances and that derived from vegetable substances?—There has hitherto been no possibility of establishing such a distinction, but this relation of nitrogen to carbon in the two classes of substances, in the peaty matters which are the common contamination of what we should call comparatively pure water, and in the sewage organic matters, I believe establishes a basis from which we can ascertain what is the kind of contamination to which the water has been subjected.

6291. Would not the organic nitrogenous sub-

stances in any of those waters be liable to putrefaction in the one case in the same way as in the other?—That is a very important point in regard to those substances. I have made numerous experiments under that head which I think have a very direct bearing upon the question which you now propose to me, and perhaps I may be permitted to state the results of those experiments, which are as follow: "If the "sewage of the 600,000 persons draining into the "Thames had the strength of average London sewage "it would amount to 18,000,000 gallons daily, and if "the average flow of the Thames at Teddington be "taken at 800,000,000 gallons daily, it follows that "the river would there contain 2,250 parts of sewage "in 100,000 parts, or $2\frac{1}{4}$ per cent. Now this sewage "as it flows into the river contains at most two parts "of organic nitrogen in 100,000 parts. This would "contaminate the whole volume of the river only to "the extent of ·045 part of nitrogen in 100,000 parts "of water. On the 21st of January last the water de-"livered by the five companies drawing their supplies "from the Thames contained the following amounts of "organic nitrogen in 100,000 parts: Chelsea water, "·058; West Middlesex, ·027; Southwark, ·061; "Grand Junction, ·031; and Lambeth, ·062." The West Middlesex and Grand Junction waters were well filtered and transparent. In very numerous experiments in my laboratory I find that a mixture of sewage with nine times its volume of water well agitated every day and freely exposed to the air oxydises but to a very slight extent. Thus immediately after mixture the contaminated water contained ·267 part of organic carbon and ·081 part of organic nitrogen in 100,000 parts, whilst after 96 hours it still contained ·250 part of organic carbon and ·058 part of organic nitrogen, and even after 192 hours the undecomposed organic matter still contained ·200 part of organic carbon and ·054 part of organic nitrogen. Consequently that portion of sewage which is not decomposed in the sewers themselves, but which finds its way into the river, is afterwards decomposed with extreme slowness.

6292. Then you conclude that it is very difficult to get rid of sewage matter by running water?—I do. That portion of it which remains undecomposed after its passage through the sewers oxydises with extreme slowness. About four-fifths of the nitrogenous matter contained in fresh sewage, which has just been produced, as it enters the sewer is decomposed before the sewage, after a run of two or three miles, emerges into the river, and the remainder, I believe, as far as my experiments teach me, is decomposed with extreme slowness afterwards.

6293. Have you not shown somewhere that the sewage which has been delivered into the Thames in the higher parts of it is almost all decomposed by the time the river arrives above London?—I have. I have reported only three times upon the presence of actual sewage in the Thames water as delivered by the water companies. On two of those occasions I reported that I could not find any trace of unoxydised sewage, but I stated at the same time that my methods did not allow me to detect a smaller proportion of unoxydised sewage than one part in 1,000 parts of water. On the third occasion I found unoxydised sewage in the water of the West Middlesex Company and reported upon it, but from the explanation of the company's engineer the origin of that sewage was traced to a broken pipe, which passing over a gulley-hole, or through a portion of the street sewer, had, during the time that the water was turned off at night, become contaminated by the contents of that sewer. Those are the only three occasions on which I have reported as regards the presence or absence of actual sewage as distinguished from previous sewage contamination in the London waters. Now the proportion which is indicated here as the normal state of things would, at that period when those reports were made, have been undistinguishable in the water by the methods of analysis then at my command; but those methods have been considerably perfected during the last four or five months, and I can now detect a smaller proportion of sewage than one part in 1,000 parts of water.

6294. Can you put in those reports?—Yes, I will do so.

6295. I see in your present reports to the Registrar General you give the organic nitrogen in all cases, whereas some few months ago you did not do so?—Yes, I commenced in the month of January last to give that in the returns.

6296. Reverting to this particular question of the presence of organic nitrogen in those waters, what do you consider to be the effect upon water of the presence of organic nitrogen, whether derived from an animal or vegetable source?—As far as we know, the presence of organic nitrogen in the form of vegetable organic matter, such as peaty matter, is innocuous, unless contained in a considerable quantity in the water; but when contained in the water in the form of sewage matter it is believed to be noxious.

6297. Did I rightly understand you to say that you cannot distinguish in those cases whether it be derived from vegetable matter or from animal matter?—I have said that until recently it had been impossible to distinguish between the two, but that now I considered that the proportion between the carbon and the nitrogen in the two cases afforded a basis from which we could, in many instances, decide.

6298. That is only an indirect method?—Yes, because the analysis itself gives no difference between the nitrogen from the two sources.

6299. In the two mountain districts you have not only the possibility of the organic nitrogen being derived from vegetable matter, but as sheep are also pastured in those districts, and there are a certain number of houses and villages, a portion of this nitrogen might be derived from those sources?—Yes, it might; but I think in such a case we should trace what we call previous sewage contamination in the water, and that has only been done in a very few cases in the samples from Wales and Cumberland.

6300. Will you be so good as to refer to the column organic carbon, where it appears that the mean maximum proportion in the London waters is ·275, and the minimum is ·143?—Yes, that is the organic carbon.

6301. Is the mean the mean for the year?—It is the mean of six months, viz., May, June, July, August, September, and October 1867.

6302. The water from Loch Katrine gives ·256?—Yes.

6303. And the water at Lancaster ·157?—Yes.

6304. And the water from the Welsh district ·460 and ·289?—Yes.

6305. And the lowest is ·227?—Yes, that is from Bala lake.

6306. Showing therefore a larger quantity of organic carbon to be present in those waters than in the London waters?—Yes.

6307. That would arise probably from the presence of peaty matter, would it not?—I believe that that is the source of the organic carbon there.

6308. Do you attach any importance to the presence of it?—I think it is very undesirable that there should be a large quantity of organic carbon in the water. I think that the water from Loch Katrine very nearly approaches the limit that one would desire to go to, because if you get beyond that amount the water becomes perceptibly tinted yellow.

6309. Would not the presence in excess of organic carbon also tend to interfere with the proper aeration of the water?—I think not; not to any perceptible extent, at least.

6310. Would it not remove the dissolved oxygen?—I do not think that the organic carbon in the form of peaty matter has much effect in removing oxygen from the water. Organic carbon in a more putrescible condition would have that effect undoubtedly, but I do not think that there would be a very marked removal of oxygen by peaty matter in the water.

6311. Then there would be no natural mode of removing this organic carbon if that were the case?—The mode which is generally considered to be effi-

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

cacious in removing this organic carbon is storage for a considerable time in large lakes or reservoirs, and there in all probability this peaty matter does undergo some slight process of oxidation by which it is precipitated. It is not completely burned up or oxydised, but it is precipitated there, and it necessitates the absorption probably of a very small portion only of oxygen to effect that change in it. At all events we found that the proportion of oxygen to nitrogen in those most peaty samples, even after they had stood for some length of time, was not different from that in spring water or in distilled water.

6312. You have expressed an opinion with regard to solid impurities. Have you any reason to believe that the quantity of organic nitrogen and organic carbon would vary according to different seasons in the year?—I should think it would not vary much in large storage reservoirs, but in the streams that have been analysed it would doubtless vary; in fact we have evidence that it does vary, in the difference that exists between the flood samples and the dry-weather samples collected in Wales from the same streams.

6313. Would it not be likely to differ very materially according to the state of the vegetation at different periods of the year?—I scarcely think that vegetation would have much effect upon this kind of organic matter in water, that is to say, upon peaty matter in water.

6314. Is not Loch Katrine water found to vary; is it not sometimes much more peaty than at other times?—I have heard it stated so, but I have never seen an actual analysis showing that difference; it may be so, and probably is so.

6315. With regard to the estimated previous sewage contamination, to which you attach considerable importance, how do you consider the nitrates and nitrites to be produced?—I consider that the nitrates and nitrites are produced by the oxydation chiefly of ammonia, the ammonia being derived from the urea present in the sewage. The urea is the first thing to decompose in sewage, and it is the form in which the greater part of the organic nitrogen in sewage is contained. This urea decomposes before the sewage leaves the sewer, in most cases, and hence it is that sewage flowing from the mouth of a sewer contains, comparatively, so little organic nitrogen, not more than one-fifth of what average sewage contains in combined nitrogen altogether.

6316. There is no doubt that that is one source of production, but are there not many others?—Yes, the oxydation and gradual transformation into mineral compounds of organic bodies containing nitrogen which are capable of that transformation. In all those cases where bases such as carbonate of lime are present in water the nitrogen takes the form of nitric acid and nitrous acid, and combines with those bases.

6317. Might not a large proportion of those nitrates and nitrites be derived from the soil?—Yes, from the manure of the soil.

6318. But might it not be derived from soil which has not been manured?—I think not, because soil which has not been manured at all contains, so far as we know, organic nitrogen in the shape of peaty matter, or *humus*, which is much the same thing; and judging from the composition of the water which we have analysed from those large lakes, that kind of nitrogenous organic matter does not pass into the condition of nitrates and nitrites, in other words, does not completely oxydise with sufficient rapidity.

6319. One source of ammonia would be, I presume, the ammonia which falls with the rain?—Yes, in rain water you have both ammonia and nitrate of ammonia and nitrite of ammonia; an allowance is made for the maximum quantity of those substances ever found in rain water, and that is deducted from the number from which this previous sewage contamination is estimated.

6320. Have any experiments been made in this country with regard to the quantity of nitrates and nitrites contained in soil which has not been manured?—Not as to the quantity contained in the soil, but I have already given the results of analyses made of water draining from such a soil. Where the soil has been drained by drain pipes, the water flowing from those drain pipes has been analysed by Mr. Way, the result of which I have already given; it indicates some small amount of previous sewage contamination—I mean small in comparison with water from manured and arable land.

6321. Messrs. Gilbert and Lawes have made a great many experiments, have they not, upon the quantity of ammonia in rain?—Yes.

6322. Supposing that the soil contains nitrates and nitrites, from whatever cause, I presume that the streams flowing from that district would be liable to contain those salts in solution?—Yes; nitrates and nitrites are readily washed out from soils, as has been shown by Mr. Way; consequently rain water draining through those soils would dissolve out any nitrates or nitrites which they might contain, and if a nitrate had been applied as a top dressing to the soil, a good deal of it would be carried out in that way undoubtedly.

6323. Are you aware of the experiments which have been made in France upon soils taken from the Vosges mountains and other districts which have never been manured, and are perfectly free from any cause of contamination of that sort, but which show the presence of nitrates in considerable quantities?—No, I have not seen the results of those experiments.

6324. Were you aware that some experiments were made a few years ago by Mons. Boussingault with soil taken in a forest of fir trees at an elevation of some thousand feet above the level of the country, and that in that soil he found a considerable quantity of nitrates?—I was not aware of those results; they are interesting in connexion with this subject, and I presume that that soil had not been, practically, at all events, manured by any considerable number of animals in the forest.

6325. No; it was just as the soil would be upon the Welsh or Cumberland hills—it had never been manured and never disturbed. Experiments were also made upon soil taken in the forest of Fontainebleau and various districts which really never had received any manuring, and yet they showed a quantity of nitrates as large in some cases as soil taken from meadows and taken from arable land?—That may be so, but that must be a condition of things which is very different from the condition that obtains in the Welsh and Cumberland districts, inasmuch as the washings from those soils in those districts contain a scarcely appreciable quantity of nitrates. I mean the washings as represented by those waters which have been collected.

6326. Might not that arise in some measure from the extremely rainy character of the district?—Yes, it might.

6327. And the salts in the other cases from the decomposition of vegetable matter probably?—Yes, probably that might to a certain extent come into play.

6328. If such be the case, it would seem that you could not very well refer the presence of nitrates and nitrites in all waters exclusively to previous sewage contamination. Without contesting that that may in many cases be so, are there not other causes in operation which may have produced the same result?—There are, undoubtedly, causes which will produce a result of that kind to a certain extent. We have the presence of those materials, as I have already mentioned, in rain water, and it is conceivable that rain water falling upon a very dry sandy district, and evaporating there mostly from the surface, might leave those nitrates behind, and they might accumulate there to some extent from that source, and they may also be produced by the decay of purely vegetable matter. This strict analysis of water for nitrates is comparatively a new thing, and it is possible that we may find sources of those nitrates which we are at the present moment not aware of. But it is a remarkable circum-

stance that waters which it is well known cannot be contaminated by manure or by sewage, never do contain those nitrates in a proportion bringing them near to the point of previous sewage contamination.

6329. Might not those nitrates also be produced by nitrogen derived from the decay of vegetable matter as well as from other sources?—I presume that they could be derived from the decay of some kind of vegetable matter, but as I have just said, I do not think they can be derived from the decay of peaty matter, because we do not find them in districts where peaty matter prevails. Where peaty water is stored for a length of time in lakes, we should expect to find in the water of those lakes a considerable proportion of nitrates, if the nitrogen in that peaty water were converted into that form of combination.

6330. But are there not plants and vegetables which contain a considerable quantity of nitrogen?—Yes.

6331. Am I to understand that you admit the possibility of those nitrates being derived from other sources than that of sewage and animal matter?—I admit the possibility of such a thing, certainly, because vegetable matters contain albumen for instance, and I can conceive that albumen in this process of decay and decomposition will give rise to nitrates, nitrites, and ammonia, but that, in this country at all events, this process goes on to any great extent, I do not believe.

6332. Still from the presence of nitrogen in rain water, and in some vegetable substances, you admit the possibility that nitrates might have a vegetable as well as an animal origin?—Yes; I admit the possibility, and I distinctly allow for the nitrogen in rain water. In all determinations of previous sewage contamination, it is not merely admitted, but always allowed for.

6333. There is another source of nitrates which I should like to ask you a question upon. Do you know what results the analyses which have been made of chalk or some of the marls or oolites give, whether they show the presence of nitrates?—If the question refers to dry chalk, I have not seen those analyses, but I can readily conceive that there may be a considerable quantity of nitrates present in chalk under such circumstances.

6334. I would refer you to the same authority, Mons. Boussingault, who made some experiments upon the chalk at Meudon, near Paris, and upon some of the marls in other parts of France. In the chalk at Meudon he found a certain proportion of nitrates, and again in the marls he found a still larger quantity, but it was not of constant occurrence?—There have been recently some important investigations made by Mons. Béchamp on the condition of chalk, even taken from great depths, and Mons. Béchamp believes that he has proved that chalk is full of living organisms, that is to say, organisms living at the present moment; at all events, he certainly has proved that chalk can act as a ferment, and can convert sugar into butyric acid, a process which we have very strong reason to believe, after long researches, can only be accomplished through the intervention of living organisms.

6335. Would not therefore the presence of nitrates in chalk or in certain soils account sometimes for its presence in streams and springs?—Yes, and I would not at all distinguish in a sanitary manner between nitrates derived from putrefying animal matter, such as dead dogs, for instance, and nitrogen derived from the putrefaction of manure or sewage. I think, so far as our knowledge extends, that the deleterious character of the waters containing any of those matters in solution is pretty nearly equal. If the chalk, for instance, contains a vast number of living organisms, it is conceivable that those organisms in their decay may give rise to quantities of nitrates and nitrites and of ammonia, and it may be that some of those matters found in the chalk water are derived from this source; but I would not on that account think that a water was preferable because it had been only in contact with putrefying animalculæ rather than in contact with putrefying sewage.

6336. You are assuming, are you not, that there is putrefying animal matter in the chalk independently of sewage, a position which has not been at all proved?—We know that sugar can be converted into butyric acid by bringing it into contact with putrefying cheese, and we now know that it can be equally converted into butyric acid by bringing it into contact with chalk, therefore the inference is very strong, although I am ready to admit that it is not absolutely conclusive.

6337. How could the animal matter in the chalk have been derived. Any of the organisms originally present in the chalk would no longer supply nitrogen in that form?—No; the nitrogen supplied to these living animals could only be derived, as far as I am aware, from nitrates and nitrites of ammonia contained in the rain water falling upon the chalk, in the first place; and secondly, from nitrates and nitrites in the drainage water subsiding into the chalk from the surface; but I think that those two would be available sources for the acquisition of nitrogen by such organisms. So far as we now know those organisms are not capable of assimilating elementary nitrogen as it exists in the atmosphere.

6338. Do not springs, although away from all sources of sewage contamination, frequently show the presence of nitrates?—I have never yet found an instance of such a spring. I have examined several springs which have been very noted for the water which they deliver being very palatable, and I found in those springs quantities of nitrates and nitrites; but I found that those springs derive their water from manured land, in all cases where I have found those nitrates and nitrites, but I have investigated spring water only to a slight extent.*

6339. I may mention that the same authority gives instances of springs away from all such sources of contamination, yet containing a considerable quantity of nitrates?—I am not aware of any such case, but perhaps I may mention in connexion with this matter that the quantity of nitrates and nitrites existing in some of the well waters of London is shown by the analyses of Dr. Letheby. There is a pump in Aldgate which exhibits a previous sewage contamination amounting to 38,080 parts out of every 100,000 parts.

---

* Since the above answer was given I have analysed a sample of spring water issuing from Mother Ludlaw's cave, which supplies Mr. Bateman's house at Moor Park, near Farnham. The spring issues from the far end of a deep cave, from a cleft in the lower greensand rock, and is fed by the water falling on a heather-covered barren moor, and filtering through the sand several hundred feet in thickness. The following are the results of the analysis:—

	In 160,000 parts of water.
Total solid residue	4·55 parts.
Organic carbon	·030 ,,
Organic nitrogen	·010 ,,
Nitrogen as nitrates and nitrites	·034 ,,
Ammonia	·001 ,,
Total combined nitrogen	·045 ,,
Previous sewage contamination	·30 ,,
Hardness	·7 ,,

We have, therefore, here an example of a spring water which has been extensively in contact with peaty matter, but which exhibits only a mere trace of previous sewage contamination, and which is in several respects superior to both the Welsh and Cumberland samples. I have also referred to the results of M. Boussingault's analyses of spring water, quoted by Mr. Prestwich, and find that out of 21 samples analysed 10 were perfectly free from previous sewage contamination. On the other hand, the spring forming the source of the But at Montmartre in Paris had a previous sewage contamination of 85,310 parts in 100,000. It may also perhaps be worth while to give the following estimations of previous sewage contamination, calculated from M. Boussingault's analyses:—

	Previous sewage contamination in 100,000 parts.
Artesian well at Grenelle	0
Source of the Presle, Eastern Pyrenees	0
The Rhine at Bâle	0
The Nile	700
The Seine at Notre Dame	1,200
The Ourcq—supplied to Paris for street watering and ornamental purposes	1,910
Well in the Rue Traversine, Paris	299,780

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

This water has been in contact with an amount of decaying animal matter which would be represented by the decaying animal matter in 38,080 parts of average London sewage. The pump in the Heralds' College yard exhibits a previous sewage contamination of 63,620 parts. The one in Leadenhall Market, 57,370. The pump in the Minories, 57,060. The one in St. Nicholas Olave churchyard, 75,640, (and this brings us into contact with another source of nitrates, namely, the putrefaction of animal remains, the remains of actual flesh and blood,) and the pump in the Guildhall Buildings, 5,140 parts.

6340. All those are from sources, are they not, where there would be every probability of the presence of animal organic matter in considerable quantities?—Yes.

6341. Therefore that is where you would expect to find a maximum quantity of nitrates?—Yes; that is in fact what has confirmed the original notion that I formed on this matter, that where such contamination is very obvious there we find it to a great extent, and where such contamination cannot be supposed to exist there we do not find it. But if there are springs which have been examined and which are free from animal organic contamination, and yet exhibit nitrates and nitrites amongst their constituents, I am quite free to admit that those would be cases certainly which would throw some doubt upon this proposition.

6342. In the cases which you have just quoted would not the quantity which you give here for the Kent water, namely, 3,393 parts of previous sewage contamination, be out of all proportion if you ascribe it entirely to such a source?—I think not. I should rather be inclined to expect more than that, and I believe that there would be more than that if it had not filtered through a very extensive stratum of chalk, because in the analyses of water which has drained through cultivated land we find, as I have already stated, an average sewage contamination of 20,370, and through unmanured pasture land, 830. You are aware, and are much better able to judge than I am, of the extent to which the water which collects in the chalk percolates through arable and manured land, or percolates through unmanured land. I spoke to Professor Ramsay upon the subject a short time ago, and he considered that the great bulk of the water would pass through cultivated and manured land into the chalk, and in that case we should rather expect a greater amount of sewage contamination, inasmuch as the average sewage contamination in water running from the drains of manured land is 20,370, and here we have only between 3,000 and 4,000.

6343. But a large portion of that would pass into the streams of the district, would it not?—Those waters that I give here are waters which do not in that way pass into the streams of the district, but which have soaked through the soil and run out of the drain pipes.

6344. Where you would have the maximum amount of contamination?—Yes. I suppose that which would run over the surface into the streams of the district would probably contain less of the nitrates.

6345. The proportion of nitrates and nitrites appears to be tolerably uniform whether you take the water from the New River Company or whether you take it from the Thames?—There is no very substantial difference between the previous sewage contamination of the Thames and of the New River; but there is a very substantial difference between that of those two rivers as compared with the water from the chalk, the Kent Company's water, and still more as compared with the water which is pumped at Grays by the South Essex Company. The contamination is about three times as great in the chalk water pumped at Grays as it is in the case of the Thames water or in the water of the river Lea.

6346. Is not the water from the spring at Grays more likely to be removed from any sources of sewage contamination than either of those other waters?—I am not so sure of that, because the whole of the sewage from London passes into the Thames at a point considerably above Grays, and there is some evidence of communication between the bed of the Thames and the water in the chalk. This has been traced with very considerable probability in the chalk wells in the Woolwich Arsenal by Mr. Abel; so that if we are to assume that there are any fissures in the chalk through which the Thames water can make its way into those wells of the South Essex Company, that in itself would account for a good deal of this previous sewage contamination.

6347. The Thames water at Grays is brackish water, and the spring would show the presence of chlorides, would it not?—I have never estimated the exact amount, but it contains a considerable quantity of chlorides.

6348. But not more than other chalk waters around London?—I am not aware.

6349. Do you trace any connexion between the previous sewage contamination in those cases and the organic nitrogen actually present in the waters?—Not necessarily. On the contrary, probably the amount of organic nitrogen present in a water is in the case of those waters which are supplied to London generally almost inversely as the quantity of previous sewage contamination exhibited by the water, because chalk waters are remarkably free from organic nitrogen.

6350. According to the table of analyses in the report which you have made to this Commission, those waters which contain the least organic nitrogen contain the largest quantity of nitrates?—They do; but those waters have been filtered through chalk; at least we may presume that they have to a certain extent been filtered through chalk.

6351. In the case of those Thames waters where you have found the greatest evidence of what you consider previous sewage contamination, should you not expect to find also the greatest actual impurity arising from sewage matters?—That would depend upon the efficiency with which filtration had been performed upon those waters. Referring to my report for the last month upon those waters, you will find that the Lambeth Company's water and the Southwark and Vauxhall Company's water contain by far the largest quantity of organic nitrogen. The Lambeth water, a specimen of which you have upon the table, contained ·062 part of organic nitrogen in 100,000 parts, and the Southwark and Vauxhall Company's water ·061. Those waters were very turbid. The Chelsea Company's water was also turbid, but less so than the two samples to which I have just alluded, and that contained ·058 part of organic nitrogen. On the other hand, the West Middlesex water was perfectly transparent, and it contained but ·027. The Grand Junction water was also transparent, and it contained ·031. It is therefore evident that the organic nitrogen in those waters is to a considerable extent contained in the form of suspended matter which is removed by filtration.

6352. Some difference exists, does there not, in the opinion entertained by medical men and chemists with regard to the effect on health of soft and hard waters?—There has been some difference of opinion on the subject, but I think the general impression now is that there is not much to be said upon that point, that they are equally good as regards their effect upon health.

6353. Are one set of waters likely to be freer than the other from the growth of vegetable substances or absorption of gases?—Hard waters will not absorb gases so readily as soft waters; but if the question relates to the absorption of sewer gases, for instance, I do not think there is the same amount of difference with regard to danger from the absorption of those gases, because, as I have said before, the noxious qualities of those gases probably reside in suspended solid matters which are carried along with the gases, and those would be equally absorbed by both qualities of water, although the gases themselves would be much more readily absorbed by a soft water.

6354. It has been supposed, has it not, by some persons that a certain quantity of carbonate of lime is desirable in drinking waters, with a view to the forma-

tion of bone, but that I presume is now not at all insisted upon, because it is perfectly well known that the lime can be derived from a number of other substances. Therefore that is perfectly immaterial?—I think it is quite immaterial from that point of view. There have been opinions advanced that hard water is productive of calculous concretions, and Mons. Belgrand in discussing the water supply of Paris mentions as a notorious fact that the people of hard-water districts suffer very much from carious teeth; but I think that those are things which are exceedingly difficult to prove, and the imagination may have a good deal to do with the opinion.

6355. Have you any reason to suppose that hard water as drinking water might exercise, not any direct influence in the way of supplying carbonate of lime to the body, but in taking away less organic or mineral matter from the body than soft water?—I have never considered the subject from that point of view, I confess; but the quantity of matter dissolved in the hardest water ever used for drinking purposes is such a very small fraction of the total solvent power of the water, that I should not imagine that there could be any substantial difference between the two kinds of water in that respect.

6356. Have there been any experiments upon that point?—No, not that I know of.

6357. You expressed an opinion just now with reference to the relative merits of hard and soft water in manufactures?—Yes; I think that for manufacturing purposes there cannot be the slightest doubt that soft water is very much preferable.

6358. To what extent do you apply that rule, as a general rule or in particular cases?—I think it applies in almost all cases. I believe that in dyeing operations there are some particular styles of work, as the dyer calls them, some particular tints in madder colours for instance, which can be better brought out by a chalky water, and some dyers are in the habit of actually putting chalk into the water that they use for the purpose of dyeing those particular tints. But those are exceptional cases, and possibly also are grounded rather upon habit in particular manufactories than upon any well-ascertained fact.

6359. Are you aware that Amiens and Lyons, which are two chief seats of the dyeing manufacture in France, the one of silk and the other of carpets, are both situated in districts where the waters are hard, the one in a chalk district and the other in a district of calcareous marls and limestones?—I think that probably the case may be very similar in dyeing to what it is in the case of brewing tea. It is generally held that soft waters make better tea than hard waters, but I do not think that, as an abstract proposition, that is the case. I think that both waters are capable of making equally good tea, but the difference depends upon the length of time that the brewing is conducted. A hard water requires to be longer in contact with the tea at an elevated temperature than a soft water does, and there may be some influence of that kind in dyeing, so that by prolonging the operation you get an equally good result, and it may be perhaps in some cases a better result from hard water than you can get from soft water.

6360. What is the case with regard to brewing?—With regard to brewing, the case I think is this, that where you want to brew a pale ale it is absolutely necessary to have hard water, and not merely hard water but water that is permanently hard, that is, water which contains sulphate of lime; but in brewing any other kind of ale, where the colour is not of importance, probably soft water is best to be used as extracting a greater amount of matter from the malt.

6361. With regard to the use of water in making tea, you have expressed your opinion that both hard and soft water may be used with pretty nearly equal advantage, but that the brewing of tea requires much longer time with a hard water than it does with a soft water; is not the flavour of the tea more delicate when made from a moderately hard water?—I do not think it is if the brewing be sufficiently rapid in the case of soft water. I have experienced that during my residence in Manchester and also in London. In brewing tea with the London water, which I suppose would probably be softened down to six or seven degrees of hardness, or seven or eight degrees at all events, if the boiling has been continued for half an hour, the length of time during which the tea ought to be brewed to get the most delicate beverage is not more than five minutes, and therefore with a very soft water like that supplied to Manchester it ought not to be more than two minutes. In fact I remember that the best tea was obtained there by pouring the water on to the leaves and almost immediately off again. If you allow a soft water to remain upon the leaves for 10 or 15 or 20 minutes you get a bitter principle out of them, which is unpleasant to me, although I believe it is pleasant to some tea drinkers. Some tea drinkers think that kind of tea the best, and that is more easily got out by soft water than by hard, and therefore from that point of view it might be said that the tea would be more likely to be spoilt by hard water than by soft.

6362. With regard to the relative merits of soft water and hard water in washing, in the consumption of soap, you are of opinion, are you not, that there is great advantage in the use of soft water?—Yes, I believe that in that respect there is a very decided advantage, not merely from an economical point of view but even perhaps from a sanitary point of view, inasmuch as a thorough cleansing of the skin I believe to be entirely impossible with hard water. The decomposition which takes place between the soap and the hardening ingredients of the water produces an insoluble material, which is actually precipitated within the pores of the skin, and to some extent at all events blocks up those pores, and does not leave the skin in a clean condition.

6363. Are you speaking now of water of a moderate degree of hardness, like the Thames water?—Yes, I never wash in the Thames water if I can help it without softening it by the addition of soda to it, on that account; I always add a few grains of soda to the water before washing.

6364. Does not a good deal of the preference which may be given in that respect to the one or the other depend upon custom?—No doubt something depends upon custom, but still I think that the curdy matter which is formed in washing with London water with soap must be unpleasant to everybody; a scum floats upon the surface when you are washing with hard water which is never formed upon a soft water.

6365. But after the first effect of it has passed away, does not the water become softened by the continued operation of washing?—That I believe to be rarely or never accomplished in ordinary ablutions, the quantity of soap that you require to add to the water to accomplish that would be too great; you would get such a mass of this scum floating upon the surface as to render washing in that water which had been thus softened by soap alone a very difficult operation. I think the water always remains hard to the end of the process of washing.

6366. Have you made any direct experiment upon that?—Yes, I am sometimes compelled to wash in this hard water; if it is cold you cannot soften it. You require to have it warm in order to soften it, and I always find at the end of washing that the water is as harsh and grating to the skin practically as it is at the beginning.

6367. But it is only by feeling that you judge of that?—Only by feeling, I have never actually experimented upon it.

6368. You have I presume seen various estimates of what might be the saving if soft water were used instead of hard water?—Yes.

6369. Do you think that those estimates are as generally correct, or do you consider them as rather in excess?—I think that there ought to be considerable latitude allowed in them. I do not think that the estimate would be correct as regards the amount of soap used in personal ablution, for the reason which I have just now mentioned. It is somewhat different in the case of washing linen. Supposing that the water were

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

not softened with soda, then I believe that the estimate would be correct, because you must get the whole of the lime salts precipitated in the water before this washing of the linen can be effectually carried out.

6370. (*Sir J. Thwaites.*) If I rightly understand your answer with reference to the river Thames, it is to this effect, that by reason of the large amount of sewage that finds its way into the river it is rendered unfit for domestic use?—Yes, that is so.

6371. And when once sewage finds its way into the river, it is very difficult to say where it will end?—It is very difficult to say; in fact, it is impossible to say that that sewage is ever got out of it again.

6372. Then you do not accept the theory that sewage discharged at point A, and travelling down the river, is so oxidised as it passes a distance of six or seven miles, and is so entirely destroyed that its original elements are not to be found, but it is converted into some other substance or substances which are not detrimental to human health?—I believe that that is by no means a generally true proposition. I believe that under favourable circumstances, that is, when the water is warm, and there is a large volume of water, and the water is a good deal agitated in its course, that effect may be produced so far as regards the dead organic matter in the sewage, but not at all as regards the living germs that may be present in that sewage. To illustrate what I mean, I will say that if you were to break an egg and beat up the contents, and mix them with Thames water at Oxford, the organic matter so introduced into the Thames might under favourable circumstances and probably would be entirely destroyed and converted into mineral matter before it reached Teddington; but if you were to throw an egg in without being broken, it would be carried down by the stream and would reach Teddington with its vitality undestroyed. That is an extreme case, but I imagine the same kind of thing to take place with regard to the unorganized portion and the organized and living portion of organic matter in sewage.

6373. Then is it your opinion that the statement is untrue that the sewage poured into the river at Windsor cannot be found seven miles below?—As a general proposition I should say it is untrue.

6374. Still I presume you are of opinion that water whilst it is flowing undergoes a self-purifying process when passing through the air from different parts of the surface becoming exposed to the atmosphere?—Yes, all the dead organic matter is constantly undergoing a slow process of oxidation; but as I have just now mentioned, in connexion with some experiments of my own on that subject, the process of oxidation is by no means so rapid as is generally supposed, because even after 190 hours, which I presume would be much longer than the time taken for sewage to flow even from Oxford to Teddington, the process of oxidation in the laboratory, with a temperature much higher than that which obtains in the Thames generally, because the temperature of the laboratory during this experiment was between 20 and 25 degrees centigrade, had proceeded to a very slight extent only.

6375. Then your general objection to the Thames water is on account of its sewage contamination, the result of human excreta?—That is the principal objection to be taken to it with regard to its effect upon health. Then as regards economy in washing and cleansing operations, there is its hardness also to be taken into account.

6376. Supposing the sewage were diverted from the Thames in pursuance of the existing law as carried out by the Thames Conservancy Board, would your objections be removed with regard to the Thames water being suitable for the supply of London?—They would be removed so far as the actual sewage was concerned. I should still object, although in a mitigated degree, to the drainage from cultivated land flowing into the Thames. But in speaking of the diversion of the sewage from such towns as Oxford and Windsor, the mere diversion of that sewage so as to throw it upon land, and then allow it to drain or to make its way into the Thames, would not overcome my objection to the water on the ground of the sewage, because I do not think that sewage which has been merely passed over land, or even through land, can be safely allowed to mix with water that is to be employed for domestic use.

6377. Then your gathering ground for the supply of large towns must necessarily be very limited if that view prevailed, that it should pass over no cultivated land, and that the smallest particle of sewage makes it unsuitable for domestic purposes?—If you have no choice of water, of course it would be much preferable to drink water that was contaminated only from the drainage from manured land, as compared with that which was contaminated directly by sewage. But sewage that has been allowed to flow over land, and which perhaps does not sink into the land at all, would, I should think, be much more objectionable than the water drainage from cultivated land, and which is manured principally from animal as distinguished from human manure.

6378. In the case of the 250 acres of land at Croydon upon which the sewage of that town is spread, the water running off into the Wandle is to the eye perfectly pure; have you ever examined any of that water to ascertain whether there is still held in solution that which is prejudicial to human health?—I have examined that particular water which you have mentioned, and also a number of other similar waters running off land upon which sewage has been placed. Those examinations have been recently made by Dr. Odling and Dr. Letheby and myself for the Board of Conservators of the Thames, and I may say that the substantial result, at least what I myself would say was the substantial result, of those examinations is, that about four-fifths of the sewage matter is destroyed under favourable circumstances, but that is all you can calculate upon. So that if you were to have all the sewage which is at present poured in an unmitigated form into the Thames distributed over the land as it is done at Croydon, you would reduce the amount of contamination of the Thames to one-fifth of what it is at present. In other words, if the population increased to five times its present amount, in the Thames basin the contamination would be as great as it is at the present day, after the sewage had passed over the land.

6379. Had the land taken up the ammonia?—The land had taken up a large amount of the ammonia, not the whole of it. It had taken out a great deal of the organic matter, amounting to four-fifths on the average, but had left the remaining fifth in, and I think that such water flowing, as we found it flowing in those cases, into the river Thames, would be an exceedingly objectionable thing to have in a river that was to be used for drinking purposes, but not at all objectionable as regards a river used for other purposes, or merely as an ornamental stream. I mean that it would be no nuisance to the inhabitants upon the banks.

6380. (*Mr. Harrison.*) With reference to the sewage contamination, I observe that in one of your weekly reports, taking first the one dated the 4th of May 1867, you refer to the water of the Chelsea Company as having an amount of sewage contamination equivalent to 2,195 lbs. of average filtered London sewage, and you add to that that "by gradual oxyda-"tion, partly in the pores of the soil, partly in the "Thames or its tributaries, and partly in the reser-"voirs, filters, and conduits of the company, this "sewage contamination has been entirely converted "into comparatively innocuous, inorganic compounds, "before its delivery to consumers," inasmuch as the expression "comparatively innocuous" is indefinite; what value are we really to attach to that term "comparatively innocuous?"—I may mention that my motive in using that word "comparatively" was to steer quite clear of a difference in opinion amongst medical men as regards the effect of nitrates upon the system. It is held by some medical men that they are peculiarly injurious, whilst others consider that they are innocuous. I confess myself that I do not think that they are at all injurious, but I wished merely to put the matter in that way, as showing that at all

events if they are at all noxious they are, compared with the original sewage, innocuous.

6381. Still we may take that as your own opinion; but going a degree further, supposing that the Thames water were properly filtered as you here suggest, partly in the reservoirs, filters, and conduits of the company, do you consider that that water (not taking exceptional cases) is innocuous so far as health goes?—I do not. I only consider that the products of the decomposition of this particular quantity of sewage which is present in the water as its skeleton, as I have called it, are innocuous; but the remaining unoxidysed portion of the sewage, if such should exist in the water, would of course not be innocuous. This statement leaves quite untouched the question whether there is undecomposed sewage in the water or not. As I have stated, I have only reported on that point on three occasions; and this statement is put in order that no one may imagine that all this quantity of previous sewage contamination means contamination which exists at the time that the water is taken for analysis. It is to prevent that impression that this explanation is given with regard to that particular part of the sewage.

6382. And with regard to that which you do say is injurious, you are hardly able to detect it?—Only rarely. Those waters are examined only on 12 days out of the 365, that is one point that must be taken into consideration. And I have only, in the case of the entire water supply, been able to get evidence which I consider anything like conclusive on this one occasion to which I have already alluded, namely, last month, on the 21st of January, when those waters contained this large proportion of organic nitrogen as compared with the organic carbon which they contained.

6383. That case to which you refer in January was quite exceptional, as I gather from your report of the 31st of January?—Yes; during the whole of the three years that I have examined these waters I have never found them in so bad a condition as upon that occasion, or in a condition approaching to that, but I may say that this condition of things having once set in, lasted the greater part of a month.

6384. In this report of the 31st of January you again repeat the words which I have just quoted; after giving the amount of sewage contamination in the water of the Chelsea Water Company you say: "By "gradual oxydation, partly in the pores of the soil, "partly in the Thames and its tributaries, and partly "in the reservoirs, filters, and conduits of the com- "pany, this sewage contamination had been converted "into comparatively innocuous organic compounds "before its delivery to consumers," and I think I find that almost word for word in all your weekly reports?—It is copied, in fact, from one to the other, it goes through the whole of them.

6385. Would that not rather lead the public to take it that your view was that this water was perfectly wholesome, or as nearly as possible perfectly wholesome?—I think it would, and that was the impression which I intended to convey, so long as I had not actually detected the presence of sewage matter unoxidysed in the water, at all events I was very anxious not to convey the impression that analysis had discovered anything actually injurious in the water.

6386. Do you agree with those remarks of your friend Dr. Odling, which are separate from your report, "Although London is at present provided with "an agreeable and in my opinion perfectly wholesome "water," &c.?—No. I do not consider it a perfectly wholesome water, I did not at the time this was written, and that, I believe, caused my colleague to give a separate postscript to this report.

6387. Have I hit upon the words of his report with which you rather disagree?—That was one of the principal points upon which we disagreed. At that time I could not go so far as to adopt that opinion of his, and now I could far less do so. Now I consider that the presence of unoxidysed sewage in the water is almost absolutely demonstrated.

6388. That is during this particular month of January?—Yes.

6389. In the month of January this year in your report you say: "The waters delivered in London "during the latter part of January by the Chelsea "and especially by the Southwark and Lambeth com- "panies, were in such a muddy condition as to render "them totally unfit for domestic use." On that point filtration properly carried out would have met, would it not, that part of your objection as to the water being muddy?—Yes, certainly.

6390. From that we may gather, may we not, that your view would be that the question of the proper filtration of the waters is one of vital importance?—I think it is a very important point.

6391. You also state in your annual report: "The "New River Company stands alone in the perfection "of its filtering apparatus. On no occasion during "the past year has this company's water exhibited "the slightest turbidity, thus proving that perfect "filtration is compatible with the largest daily supply "furnished by any one company in London." Do you see any reason why every company should not give out their water in the same perfect state that you here describe the New River Company does?—I see no reason whatever why the other companies should not.

6392. And do you consider that it would be a desirable thing in case of necessity that such a delivery of water in a pure state should be enforced by legislative enactment?—I do; in fact it is so enforced at the present moment.

6393. You also say: "The seven companies who "occasionally or habitually send out turbid water "subject the inhabitants of more than 300,000 houses "to the unnecessary expense of private filtration?"—Yes.

6394. Going back now to the words which you use in your report of January the 31st, that the waters of the other companies that you mention "were in such a "muddy condition as to render them totally unfit for "domestic use," you are clearly of opinion that that is an objection which might be met by adopting a proper method of filtration?—Yes, so far as muddiness is concerned it could be completely met.

6395. Then you describe the causes of this peculiar state of things in the month of January: "The "Thames has overflowed its banks above the point at "which the water supply is withdrawn, and by wash- "ing the surfaces of cultivated fields, and mingling "with the contents of stagnant ditches and ponds, has "become contaminated to an intolerable degree. Those "companies which, like the West Middlesex and "Grand Junction, possess ample and efficient filtering "apparatus, were enabled so far to cope with the "difficulty as to send out their supply free from sus- "pended matters. A week later, however, than the "date when the samples were collected the water of "the Grand Junction Company had also become "turbid, but much less so than that delivered by the "Southwark and Lambeth companies." This is the period during which you state that you found these waters to be in an unfit state?—It is.

6396. Assuming that the Act of Parliament which was passed last session for preventing the pollution of the river Thames is efficiently carried our, and that no sewage is directly discharged into the river, and assuming also that those companies adopt proper modes of filtration, would not this specially objectionable case be to a great extent met?—With regard to the muddiness of the water, it would completely, but not with regard to the wholesomeness completely. The unwholesomeness of the water would doubtless be mitigated by otherwise disposing of the sewage, or rather, I should say, by passing the sewage over the land before its admission into the Thames; but I do not think that even after that such a proportion of sewage would be innocuous when admitted into the Thames.

6397. I gather from your remarks that we are not for the future to take those words in your weekly reports in the popular sense in which one would ordinarily read them, as to the comparatively innocuous qualities of the water?—That is my own individual opinion, that the nitrates, nitrites, and ammonia are perfectly innocuous.

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

6398. Looking to future reports, and considering the views which you now entertain, we should probably not see the same words in that same form in future reports?—I think that those words will substantially be in the same form, but I shall probably now proceed to report upon the unoxydised sewage. These words refer only to the oxydised and decomposed sewage. I have hitherto refrained entirely, except in the three cases which I have mentioned, from saying a word about the unoxydised sewage, because it was present in such small quantities that I did not consider that the indications which I had of it were outside the errors of experiment. But now, during the next few months or during the present year, if I find further evidence of this actual sewage contamination, as I term it, in contradistinction to previous sewage contamination, some remarks upon that point will no doubt appear in those reports.

6399. Is it not quite possible that with an exceedingly large amount of previous sewage contamination the water may still be perfectly harmless?—It is possible, that is to say, on certain assumptions.

6400. May we not assume that, however contaminated the water may have been upon your principle of previous contamination, still you may find it on analysis to be perfectly pure and wholesome?—Yes; for if the water had been boiled for an hour or two it would still exhibit the same thing as previous sewage contamination.

6401. Or by a large extent of filtration through a very extensive porous soil?—Yes, but I should not be prepared to say that after any amount of filtration we should be guaranteed from the presence of those minute germs, which being smaller in some cases, as they have been proved to be, than blood globules, would pass through the pores of the chalk, for instance, like human beings pass through the streets of London.

6402. Still you are not able to detect those globules?—No, they are beyond the reach of the chemist, and so far of the microscopist, I believe.

6403. They must have existed in the sewage in some form or other previously, must they not?—It is not certain that they exist in all sewage; in fact, we may say that the particular germs which are believed to give rise to such diseases as typhus fever and cholera have never been actually identified in water at all, or in sewage even.

6404. Might not we, perhaps, take it that your view is rather a negative than a positive one as to the danger from using that water, rather in this sense, that it is not positively a dangerous water, but that it may contain the germs of danger in it?—Yes; I would not say that that particular water on the table, which is the worst sample, perhaps, certainly the worst sample I have met with, could not be drunk with impunity; we have no evidence to show that it could not be so drunk with impunity; but if that water were in that condition during a period of epidemic cholera, and the discharges of cholera patients had got into it, it would be exceedingly probable, although even then it would not be absolutely certain, that that water could not be drunk with impunity.

6405. Will you be good enough to give us a reference to those three cases which you have mentioned; are they referred to in the Registrar General's weekly reports?—Yes, they are all in the weekly reports. I am afraid I have not the weekly report which contains the exact words used in my report upon those cases, but this is as nearly as possible a copy of them as contained in a published lecture of mine upon the subject, delivered at the Royal Institution not quite a year ago: "By operating upon one litre of water "for the determination of total combined nitrogen, "one per cent. of sewage can be detected with certainty; but smaller per-centages ought, in operations upon such a small quantity of water, to be "considered as falling within the possible errors of "experiment. Thus, in the table of analytical results "given below, the indications of organic nitrogen, "and consequently of present sewage contamination, "amounting in the maximum to one-half per cent., "ought to be disregarded; because as the total combined nitrogen was determined in one litre of each "water, the amount of present sewage contamination "indicated by the analysis falls within the limit of "possible experimental error. The subjoined tabulated results obtained in the analysis of samples of "the metropolitan waters collected in February last "and during the present month, show therefore that "none of these waters contained as much as one per "cent. of present sewage contamination. This "search for unoxydised sewage or its equivalent in "a water may be rendered more minute by operating "upon a larger volume of water, by which the possible error of experiment is reduced in proportional "amount; thus, if 10 litres of water be used for the "determination of total combined nitrogen, one-tenth "per cent. of present sewage contamination can be "ascertained with certainty. This operation has "been performed upon 10 litres of the Thames water "delivered by the Grand Junction Company, and "collected during the present month" (that is, March 1867), "and it is satisfactory to find that this minute "examination failed to detect any actual sewage contamination, consequently the sample of the Grand "Junction Company's water operated upon did not contain one-thousandth part of its volume of unoxydised "sewage." That was one case. The other case was a similar one, in which the East London Company's water from the Old Ford reservoir was submitted to this detailed analysis; 10 litres of it were taken, and that analysis also failed to demonstrate the presence of unoxydised sewage in that water. The other case was that of the West Middlesex Company's water collected on the 1st of June at the cab rank in Portland Road, about which the following remarks are made in the monthly report dated Saturday, June the 29th, 1867: "The "above analytical results show that the water of the "West Middlesex Company, drawn from the standpipe at the cab rank in Portland Road, on the 1st "instant, was contaminated with sewage" (present sewage contamination), "for, if the amount of nitrogen "existing as nitrates, nitrites, and ammonia (·318 "part) be deducted from the total combined nitrogen, "there remains ·103 part, which must be organic "nitrogen, equivalent to 1,030 parts of average "London sewage in 100,000 parts of the water, "or rather more than 1 per cent. The water was "turbid when drawn, and after standing for a few "days emitted a very offensive odour, and became "filled with white floculent matter, resembling that "which gradually deposits from filtered sewage. A "few days later this odour disappeared. In answer "to my inquiries the engineer of the company informs "me that a breakage had occurred in one of the "company's mains in an adjoining street, and near a "gully hole. This fracture, which was repaired on "the 3d of June, soon after its discovery, happened "to a main from which the water pressure was "removed at night, and it is believed that during "this absence of pressure sewage commingled with "the contents of the main. It is gratifying to find "this satisfactory reason for believing that this contaminated water was delivered to a small district "only, and for a short time, but this accident supplies "another item to the already long list of dangers "attending an intermittent supply of water."

6406. That would have been equally the case if you had been getting water from Wales, would it not?—Yes, on the intermittent system in that particular case.

6407. And in the case which you referred to before, they were both exceptional cases?—In the other two cases no sewage was discovered.

6408. Have you discovered this unoxydised sewage in any case in the ordinary water as supplied, where there has been no accident at all?—If you call it an accident on the 21st of January, I have not. I have not discovered it under ordinary circumstances except upon this one occasion, but there it was discovered in the water delivered by three different companies on the same day.

6409. Under the circumstances which you have described in your report which I have read of a particular flood in the Thames at the time?—Yes.

6410. I presume you know Dr. Letheby's opinion upon this question?—Yes, I do.

6411. And that he does not agree with you?—No, I do not think he does. As to the danger of contamination by sewage, in some respects he agrees with me. When we talk of well waters we are perfectly agreed about them, but with regard to river water we differ.

6412. In fact, his views would be perfectly expressed by reading what you state in your report, if I may put it in these words: "By gradual oxidation, "partly in the pores of the soil, partly in the Thames "or its tributaries, and partly in the reservoirs, filters, "and conduits of the company, this sewage contami- "nation had been entirely converted into," instead of "comparatively," "a perfectly innocuous inorganic "compound?"—Yes.

6413. If I put the word "perfectly" for "comparatively" in your case, that would express his opinion entirely upon this question?—I should have no difficulty in changing that word from "comparatively" to "perfectly," as expressing my own opinion upon the subject, certainly; but I think I have heard Dr. Letheby say that those nitrates are not perfectly innocuous when they are present in large quantities.

6414. I am taking that as his opinion as applied generally to the water of the Thames?—Yes, that small quantity he would also pronounce to be perfectly innocuous; but large quantities of nitrates are believed by many medical men to exert a deleterious effect.

6415. You do not arrive at the conclusion that the Thames water is so injurious to health that at any cost it ought not to be used?—I think if any other source were obtainable, even at a great additional cost, it ought to be preferred to the Thames water.

6416. Of course, in all this I am going upon the assumption that the Act of last session is fully carried out, which prevents the discharge of all sewage into the Thames?—If you are proceeding on the assumption that the sewage will not in any manner make its way into the Thames, that is impracticable, I believe.

6417. No, the sewage would be placed over the land and would still find its way by filtration through the soil into the Thames, and in many cases into the chalk, and that might not come into the Thames?—I should think that even under those modified circumstances the water would still be unfit for domestic use.

6418. (*Sir B. Phillips.*) You have spoken of the system of filtration adopted by the New River Company, and you say that that company stands alone in the perfection of its filtering apparatus. Supposing all the other companies were to adopt the same process of filtration as the New River Company appears by your report to have adopted, would that remove your objection?—Not entirely; it would mitigate it, but not entirely remove it, because we have no proof whatever that filtration even of the best kind can remove certain objectionable matters which are present in sewage. We know that the white rice-water evacuations of cholera patients cannot be so removed.

6419. But we are to understand you to say that it would partially remove your objection?—Yes, certainly it would; I would much rather have well-filtered water than water that is not filtered.

6420. (*Sir J. Thwaites.*) Are not all the companies under obligation to filter since the passing of this Act of 1852?—Yes, they are all supposed to filter perfectly at the present time.

6421. (*Col. Harness.*) You have alluded to some experiments which you made with choleraic matter mixed with a proportion of pure water. Supposing that mixture had been sent to you as a sample of water without your knowing how it was composed, how would you have reported upon it?—I should in all probability have reported, in fact I should certainly have reported at that time that that water was slightly turbid, but in other respects an exceedingly pure water; and even now I do not know that I could report differently upon it, because it was mixed with distilled water, and the proportion of organic matter put into the distilled water by that mixture of $\frac{1}{1000}$th part of this evacuation was so small that it would have been much less than that which was found in Thames water, and much less than that which is found in the water in Cumberland and Wales.

6422. Would you have reported that water as better than the water that is now drank in London?—Most certainly I should, with the exception of turbidity. I think that turbid water on account of its constant danger of contamination is always to be rejected.

6423. (*Mr. Prestwich.*) Might not the superiority of the New River water at the date you mention arise as much from the different source of supply as from the superior methods of filtration?—My remark is founded upon an examination of those waters during an entire year, and during the whole of the year 1867 the New River Company's water was never on any single occasion in the slightest degree turbid, but that was the case with no other water delivered in London.

6424. Would not you rather ascribe that to the circumstance that the New River water is derived principally or to a large extent from chalk springs, and does not flow over any extent of meadow land, whereas the Thames water is derived in some part from water flowing off clay land, and is subject to floodings of the marsh lands in its course?—No doubt in regard to the samples collected last January I should say so, but I have seen the New River water entering the New River head at the River Lea turbid, and requiring good filtration to render it bright, and yet, seeing that water entering their works at that point in that condition, I find that when it is delivered to the consumers in London it is perfectly transparent, and therefore I conclude that they have very efficient means of filtration.

6425. But is not a large portion of the New River water derived directly from chalk springs and wells?—I am not able to speak of the proportion of the two sources, but I know that they have several wells from which they pump a considerable quantity of water, but whether that constitutes a very large proportion of the total supply I am not prepared to say.

6426. What should you consider the essential conditions of a good drinking water?—The essential conditions of a good drinking water I should take to be, first, coolness and aëration; secondly, freedom from animal organic matter of all kinds; thirdly, that it should never have been contaminated by sewage or manure in any form; and, fourthly, that it should be soft water, not over five degrees of hardness.

6427. But have you not expressed an opinion before, that the question of hardness or softness was not important as regards a drinking water?—I beg your pardon. I thought your question referred rather to the general question. As regards a drinking water only, I should not object to a considerably greater amount of hardness than I have mentioned—it might be as hard as Thames water as a drinking water, or even harder for anything that I know, I do not know that there is any reliable evidence as to injury having resulted from drinking hard water.

6428. Should you not consider some of the chalk springs in the neighbourhood of London, or springs coming from the greensand, as furnishing water of unexceptionable quality as drinking water?—If it were not for the uncertainty regarding the possibility of filtering this noxious matter out of water, even by its passage through several hundred feet of chalk or greensand, I should undoubtedly think such water to be good water.

6429. (*Mr. Harrison.*) Is it not the fact that upon the average of the whole of last year the New River water contained a larger proportion of previous sewage

Dr. E. Frankland, F.R.S.

27 Feb. 1868.

contamination than all the rest, with one exception, taking the mean of the whole?—Yes, with one exception, namely, the Kent water; and probably the exception throws light also upon the cause of the source of contamination of the New River water, because they pump out of the chalk to some extent, as Mr. Prestwich has just mentioned. With regard to this previous sewage contamination, I ought perhaps to mention that I do not consider that this contamination is of the same value, so to speak, or ought to be looked upon in the same light in all waters. Previous sewage contamination in a water which has been but very slightly filtered is a very much graver charge to be brought against it than previous sewage contamination in a water that has been filtered through a very thick stratum like that of chalk. In fact, I have already said that I would rather drink water that was four times as much contaminated previously by sewage or manure matter, if it had filtered through a hundred feet of chalk, than I would drink water containing a smaller proportion of previous sewage contamination which had merely flowed down a river.

6430. Taking it in the form in which it appears in this table in your report, the amount of previous sewage contamination really cannot have any substantial value attaching to it to determine what is the state of the water, because you take it from all the supplies in the same condition, and then you take it from the mains as it is delivered?—This table of previous sewage contamination shows only the amount of animal organic matter with which the water has been in contact expressed in terms of average filtered London sewage.

6431. But it does not give any information as to its present condition?—Yes, also as to its present condition, which is perfectly innocuous so far as that amount of sewage is concerned.

6432. (*Mr. Prestwich.*) As regards that point of previous sewage contamination, you have just stated that you attribute this previous sewage contamination entirely to decomposing animal matter; but from your answers to the questions which I put to you before may I not fairly arrive at the conclusion that the case is altogether hypothetical?—I think what I said was this, that no doubt vegetable matter could possibly give rise to the production of nitrates and nitrites in its decay, but I believed that it was not the case to any appreciable extent in the conditions affecting water in this country, inasmuch as I find no traces or very slight traces of those compounds in water from localities where it has been contaminated only by vegetable matter.

The witness withdrew.

Professor W. Odling.

Professor WILLIAM ODLING examined.

6433. (*Sir J. Thwaites.*) You are a Bachelor of Medicine and a Fellow of the Royal Society, are you not?—Yes.

6434. And I believe you are Professor of Chemistry at St. Bartholomew's?—Yes.

6435. In conjunction with Dr. Frankland you have made analyses, have you not, of several waters collected by Mr. Pole?—Yes.

6436. Having heard the evidence of Dr. Frankland, do you generally concur in his evidence, as we may gather from your report, with regard to the analyses of the waters from the Welsh and the Cumberland districts?—Yes, quite so.

6437. Do you concur with Dr. Frankland's view of the advantage of soft water for domestic purposes as well as for manufacturing purposes?—I think that, excepting for drinking purposes, soft water is upon the whole preferable to a hard or even to a moderately hard water like the Thames.

6438. For manufacturing purposes would not soft water have great advantages over hard?—Yes, except in very special cases.

6439. On the score of health do you make any distinction between soft and hard water?—I do not think there are any facts which enable one to give a positive opinion. Some gentlemen who have considered the subject entertain very strong opinions both ways; but I do not know any facts upon which one can speak positively.

6440. You have carefully examined the waters from the sources of the Severn and the waters taken from the Lake districts, and compared those waters with the water supplied by the several companies in the metropolis, what is your opinion as to the relative values of those waters?—I would say that the waters proposed to be taken from Wales and Cumberland are sufficiently alike to be considered as one, and the waters supplied to London from the Thames and the Lea are sufficiently alike to be considered as one; and I would say that although the waters of Wales and Cumberland are in some points inferior to those by which London is now supplied, still upon the whole they are superior, more especially in consideration of their softness.

6441. Are we to understand you to say that the waters of the Lake district and the Welsh district are in some respects inferior to the water supplied to London?—Quite so, but taking them altogether they are superior.

6442. Will you be good enough to explain the inferiority?—They are less bright, they are not so colourless, and they are not so well aerated. Of course I am speaking comparatively only. They are not waters of bad colour, or bad appearance, or bad aeration, but Thames water is better in these three points.

6443. But are you of opinion that, supposing the Act of last year were faithfully carried out, and the sewage were intercepted from the river Thames, the water on the whole would be a suitable water for the supply of London for domestic purposes?—Yes, I am.

6444. Are you of opinion that the advantages of the soft water from the Lake district and the Welsh district would be worth the additional expenditure which would be involved in bringing them to the metropolis for the supply of the inhabitants?—That I can hardly say, because I have no knowledge whatever about the expenditure.

6445. But having a choice between the two waters, to which would you give the preference having regard to all considerations?—If they were both at my door, or within a mile or two, I would certainly take the Welsh or the Cumberland water in preference to the London water.

6446. But that preference is not so strong as to lead you to recommend a heavy expenditure for the selection of one as compared with the other?—It is not.

6447. You have examined the Thames water from time to time, have you not?—I have examined it fully.

6448. Have you found in those examinations of the Thames water the presence of sewage not decomposed?—I have not.

6449. Do you attach the same importance to the presence of sewage as affecting human health as that which Dr. Frankland has given utterance to?—On general grounds, I think, it would be very objectionable to drink water that was known to be contaminated with any appreciable proportion of sewage, as sewage.

6450. Have you examined the water at the point where sewage has been discharged into the river, and have you examined the same water at a distance of three or four or five miles lower down, and if so what has been the result?—I seem to have an impression of having made such experiments on some particular occasions, but I cannot call the details to mind.

6451. Has your attention been directed to the important principle of the self-purifying process which is going on in rivers running at a given velocity?—Yes, it has. There may be great differences of opinion as to the degree to which that self-purification takes place, but that it does take place to a very considerable extent I think is undeniable.

6452. You will understand my question as not referring to sluggish waters, but to rivers where the body of water would become exposed to the action of the atmosphere as it passes along?—You may see in many rivers, even sluggish rivers, having sewage discharged into them, that for a mile or two the appearance of the river is affected by the sewage, but beyond a certain distance there is no recognizable effect at all, the weeds are perfectly clean and perfectly healthy.

6453. Do you know Leicester at all?—Yes.

6454. Do you know the condition of the river there?—Yes, I do.

6455. Near to the town it was in a very bad condition, and the water quite black, was it not, when you saw it, from the refuse of manufactories and the discharge of sewage?—Yes.

6456. Did you observe the condition of that river three miles from the town?—Yes, and from its appearance you could not tell that it had been contaminated, it was running clear, with fish swimming in it, and the weeds were clean.

6457. And that simply from the process of self-purification?—Quite so.

6458. Have you ever examined the water of that river so as to detect the presence of sewage, although it appeared clear?—No, I have not.

6459. You have not detected any of the skeleton forms which Dr. Frankland has given utterance to?—That is a point on which I am a little at issue with Dr. Frankland, with regard to the interpretation to be put upon the presence of nitrates in water. It is admitted that the presence of nitrates says nothing for the present condition of water at all, and I rather dispute that it says anything very important for its history. There is no doubt that a very large quantity of sewage, or the equivalent of sewage, is discharged into the river Thames above the source of the present water supply, and I do not mean to say that Dr. Frankland exaggerates that proportion at all—I do not know whether he does or does not—but I contend that the estimation of the nitrates in a water does not give any ground on which to estimate its proportion of sewage.

6460. But when found are they in your judgment injurious to the water?—In such quantities as are found in the river supply of London they are, in my opinion, perfectly innocuous.

6461. Still less, I suppose, if found in chalk?—Yes, quite innocuous if found in chalk.

6462. Is it your opinion that those which have been found in chalk are due to sewage?—It is a point upon which there is no positive evidence, but I am inclined to think that it is not so, for we find them distributed so irregularly. For instance, the deep-well water at Trafalgar Square, and the deep-well water from the greensand, and lower chalk all over London, is nearly free from nitrates and nitrites; whereas the water of equally deep wells elsewhere in the chalk is found to contain very considerable quantities of nitrates. The deep well-water from nearly all formations has been found to contain nitrates. Then, moreover, a proportion of the nitrates which the sewage itself undoubtedly does furnish, in one case is destroyed and in another case is not; and so far as the history of the water is concerned, in the one case where the nitrates are destroyed, that water may show but a very small amount of previous sewage contamination, whereas it might have had a much larger amount than the other.

6463. Apart from the question of sewage, is it your opinion that the condition of the Thames basin is such as to render it an unfit gathering ground of water for domestic purposes?—I do not think it at all unfit.

6464. (*Sir B. Phillips.*) You state, do you not, that supposing the two supplies, the Thames and the Lea and the Lakes, were within equal distance, you would prefer the Lakes' supply to the other?—Yes, I should.

6465. Supposing that you were a London ratepayer living in an expensive district, paying say a rate of 6*d.* for the Thames water, do you think that you would feel disposed to have your rate doubled for the purpose of obtaining the Lake water?—Unless I were a manufacturer I certainly should not.

6466. As a manufacturer it would become a question of trade, of course; but supposing as a private gentleman with a family living in one of the expensive districts of London, with a house heavily rated, you had the choice of the London water at a rate of 6*d.*, and of the Lake water at a rate of 1*s.*, do you think you would pay the double rate for the purpose of having the Lake water?—I do not think I should.

6467. Then do you agree with Dr. Frankland, that supposing a system of perfect filtration were adopted (and he appears to consider that the New River Company has a perfect system of filtration), and if all the companies were to use the same process, we should have a water perfectly wholesome for domestic purposes?—Certainly I do.

6468. (*Mr. Prestwich.*) You heard the questions which were put to Dr. Frankland with regard to the quality of these waters. As to their freedom from mineral impurity there can be no doubt. Do you agree with him in his views with regard to the presence of organic nitrogen and organic carbon?—Yes.

6469. These analyses show, do they not, that in those respects the Welsh and Cumberland waters possess no superiority over the London water?—Precisely so.

6470. Do you consider that the presence or absence of these substances forms an essential consideration in estimating the quality of a water?—If a water contained a large proportion of organic nitrogen I should say it was bad.

6471. Do not you consider that the quality of water for drinking depends mainly upon the presence of organic nitrogen in it?—Yes, substantially that is so.

6472. And that the presence of nitrates, if not in excess, is a comparatively unimportant element?—It is an unimportant element as to its state, and I believe it to be in many cases an unimportant element as to its history.

6473. You have heard the questions that were put to Dr. Frankland with regard to the probable origin of nitrates. Are you of opinion that their origin may be traced to several sources?—I am quite of that opinion.

6474. With regard to the presence of nitrates in the deep chalk wells of the Kent Company that have been referred to, they show a quantity of nitrates present as large or larger as in the Thames water; but it does not follow, does it, that they are necessarily derived from the same source?—Certainly not.

6475. Is it not unlikely that at the Grenelle well, where the water rises from a depth of 1,800 feet, and the source of which is 120 miles from Paris, that the nitrates in such water should have such an origin?—I was not aware of that, but I daresay it is so.

6476. Do not you consider that it is improbable that such nitrates in water passing 120 miles underground should be derived from sewage contamination?—Yes; the quantity of nitrates found in this water and in many other deep-well waters from the new red

Professor W. Odling.

27 Feb. 1868.

sandstone, the old red sandstone, and the greensand, negatives the idea of their being always derived from sewage contamination.

6477. What do you consider to be an essential quality of good water for drinking purposes? — It should be bright, colourless, and brisk, and it should not contain any considerable amount of nitrogenous organic matter.

6478. What is your opinion with regard to the presence of carbonate of lime?—For mere drinking purposes I do not consider it a matter of any disadvantage at all.

6479. Do you think that there is no risk in using for drinking purposes waters which are derived from rivers the population on the banks of which is constantly increasing?—Of course it is conceivable that the amount of impurity discharged into a river may exceed the power of the river to purify itself, or approximate so nearly to that power as to leave a balance that it would not be safe to rely upon.

6480. Has it not been found that even with the best filtering apparatus, after a time the filter becomes clogged, and the water which passes through is apt still to retain its organic impurities?—I should think that so far as mere filtration was concerned, by a sufficiently frequent cleansing of the filter there would be no danger from inadequate filtration, even if the water were very bad indeed; but I think that the soluble matter of the sewage might in some cases become so large from the proportion of sewage discharged into the river, that the water would be quite unfit for drinking purposes, even although it was filtered perfectly.

6481. (*Mr. Harrison.*) But that would not be the case with the Thames?—No.

6482. (*Mr. Prestwich.*) The subject of the analysis of water with a view to detect organic matter is one of extreme difficulty, is it not?—Yes, of extreme difficulty, and we are all much indebted to Dr. Frankland for the great improvements that he has introduced into the mode of determining the organic matter of water.

6483. Do you think that it is capable of still further improvement?—Yes, I think it is.

6484. Do you consider that the process which has been lately introduced by Mr. Wanklyn will prove useful with further improvement?—The process which Messrs. Wanklyn and Chapman have introduced is at present in rather an immature state, but I think it very likely that with more work bestowed upon it, it may prove a useful comparative process.

The witness withdrew.

Adjourned to Wednesday next, at 12 o'clock.

Wednesday, 4th March 1868.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

J. F. Bateman, Esq.

4 March 1868.

JOHN FREDERIC BATEMAN, Esq., further examined.

6485. (*Chairman.*) When you were examined last year you promised, did you not, to produce some plans and documents for the Commission?—I did, and I shall now be happy to hand them in. The first table gives the returns of rainfall in different localities indicating the effect of mountain ranges. I tried when I first had the honour of addressing the Commission to explain the reasons why I had come to certain conclusions with regard to the fall of rain in the particular locality which I had taken for the supply of water, from the actual known fall in situations which were, as far as could be, analogous to the situation which I had chosen. I daresay it will be remembered that I pointed out various localities, in Scotland for instance, across ranges of hills, to show how the rain was greater on the westerly side than on the easterly side of a mass of mountains, and how it greatly increased in the first trough of hills and decreased in succeeding ridges and succeeding troughs. I will not, if I can help it, repeat any of the evidence which I had the honour of giving before, but I will hand in now the tables which you were then kind enough to ask for, which show the state of things which I was anxious to describe.

The first table shows the rainfall along a line commencing at Standish, near Wigan, in Lancashire, crossing the watersheds of the Liverpool and Bolton waterworks and terminating at the Blackburn waterworks, the direction being from south-west to north-east.

TABLE No. 1.

Showing the RAINFALL along a Line commencing at Standish, near Wigan, crossing the Watersheds of the Liverpool and Bolton Waterworks, and terminating at the Blackburn Waterworks; the direction being from S.W. to N.E.

Years.	Wigan Waterworks, Standish. Elevation 300 ft. above O.D.	Liverpool Waterworks, Rivington. Elevation 700 ft. above O.D.	Bolton Waterworks, Belmont. Elevation 800 ft. above O.D.	Blackburn Waterworks, Pickup Bank. Elevation 650 ft. above O.D.
	Ins.	Ins.	Ins.	Ins.
1856	—	49·60	52·5	40·1
1857	—	41·16	43·4	42·5
1858	36·10	43·60	43·7	38·7
1859	37·35	46·84	53·4	44·3
1860	46·04	51·31	59·8	55·0
1861	47·63	46·38	55·7	48·7
1862	49·01	48·51	61·9	53·8
1863	44·70	51·01	66·0	48·0
1864	34·79	39·03	48·2	34·1
1865	33·48	34·80	42·6	35·6
	This gauge is in the open country.	The above is the result of several gauges placed at different heights on the westerly side of the hills.	This gauge is in the first deep valley to the east of the first range of hills.	This gauge is in a valley further to the east, with intervening hills.

You will observe, with reference to the first column of this table, which includes the rainfall from 1858 to 1865, by a foot-note at the bottom of the column,

that this gauge is in the open country, near Wigan, Wigan being in a comparatively open country away from the hills. I have not calculated the mean rainfall, but you will be able to see it in any one year. If you take the first year, 1858, you will find the rainfall 36·10 inches. The next column is the mean of seven gauges, spread over the watershed of the Liverpool waterworks, which are placed at various elevations, but having a mean elevation of 700 feet, which is the mean elevation of that watershed; and those gauges are all on the westerly slope of the first range of hills, against which the rain clouds, coming from the Irish sea, will impinge. If you take the same year to which I have referred, 1858, you will find the rainfall 43·6, showing how the rainfall increases by the rain clouds impinging upon the western slopes of that range of mountains. The next gauge is at the Belmont reservoir of the Bolton waterworks, which is just over the summit of the first range of hills and in the first deep trough, and the rain there in the particular year which I happen to have selected, 1858, is 43·7, as nearly as possible the same as on the Liverpool drainage ground; but if you look at the next year, 1859, (and almost any other year tells the same story,) you will find that the rain in 1859 was 46·84 on the average, on the Liverpool drainage ground, and 53·4 at the Bolton waterworks. The next gauge is further to the east, and is not quite the next trough, but there are comparatively no summits intervening between it and the trough of the hills in which the Bolton waterworks are situated, and it shows for 1859 44·3. That shows the manner in which the rain gradually increases under certain physicial conditions, and how it decreases the further you go in an easterly direction.

The next table shows the rainfall along the line of the Rochdale canal across the Penine chain of hills from Rochdale, at the foot of the western slope to Sowerby Bridge at the foot of the eastern slope of hills.

Table No. 2.

Showing the Rainfall along the Line of the Rochdale Canal from Rochdale to Sowerby Bridge. Direction from S.W. to N.E.

Years.	Rochdale.	WhiteHolme, Blackstone Edge.	Toll Bar, Blackstone Edge.	Black House, Blackstone Edge.	Sowerby Bridge.
		Elevation 1,200 ft. above O.D.	Elevation 1,000 ft. above O.D.	Elevation 1,000 ft. above O.D.	Elevation 300 ft. above O.D.
	Ins.	Ins.	Ins.	Ins.	Ins.
1846	31·7	43·2	43·9	42·5	27·90
1847	31·3	47·8	48·1	46·3	29·38
1848	39·7	66·7	67·5	66·6	32·27
	At foot of hills, westerly side.	Near summit of hills.			At foot of hills, easterly side.

I need not go over the whole of those columns, but I would merely mention, alluding to the foot-note at the bottom of the first column, that the Rochdale gauge is at the foot of the hills on the westerly side. The three next gauges are near the summit of the hills, and they all show a very considerable additional quantity of rain to that which occurred at the foot, and they are pretty nearly all on the same level. The next gauge, at Sowerby Bridge, which is at the foot of the hills on the easterly side, and where the rainfall is less than at the westerly foot, speaks for itself.

The next return which I have to hand in shows the rainfall along the line of the Manchester, Sheffield, and Lincolnshire railway, through the Longdendale Valley, in which the Manchester waterworks are constructed, almost direct west and east, and in the valley of the Don down to Sheffield. It shows the manner in which the rain increases towards the head of all valleys which are land-locked by hills of considerable elevation.

Table No. 3.

Showing the Rainfall along the Line of the Manchester Sheffield and Lincolnshire Railway, from Manchester along the Longdendale Valley, in which the Manchester Waterworks are constructed, to Sheffield. Direction from W. to E.

Years.	Manchester. Elevation above O.D. 194 ft.	Manchester Corporation Waterworks. Rhodes Wood Reservoir. Elevation above O.D. 500 ft.	Manchester Corporation Waterworks. Woodhead Reservoir. Elevation above O.D. 800 ft.	Stations of the Manchester, Sheffield, and Lincolnshire Railway. Woodhead. Elevation above O.D. 939 ft.	Dunford Bridge. Elevation above O.D. 954 ft.	Penistone. Elevation above O.D. 717 ft.	Sheffield. Elevation above O.D. 288 ft.
	Ins.	Ins.	Ins.	Ins.	Ins	Ins.	Ins.
1859	38·63	46·34	53·35	57·64	58·56	39·66	25·11
1860	41·40	47·85	53·69	66·35	62·79	30·11	27·58
1861	34·43	40·22	44·24	49·64	47·88	27·02	25·55
1862	43·95	47·28	49·63	48·51	52·55	29·09	28·93
1863	44·71	48·04	53·77	55·07	59·46	32·26	30·87
1864	34·33	38·50	43·52	39·98	39·21	24·80	22·56
1865	27·27	37·25	40·35	36·79	41·44	26·73	26·81
1866	43·64	58·45	64·58	66·39	67·15	41·85	33·12
1867	31·47	49·55	55·96	52·83	55·94	28·46	29·96
	In the plain.	In the valley of Longdendale.			In the valley of the river Don.		

If you take the first year, 1859, from that table, it appears that the rain at Manchester was 38 inches in round numbers; at the Rhodes Wood reservoir, which is the lowest of the reservoirs, it was 46 inches; at the Woodhead reservoir, which is a reservoir second above that, 53·35 inches, and at Woodhead, which is a little higher than the reservoir at the upper end of the valley, it was 57·64 inches. From that point the hills rise abruptly, and then just over the hills, at Dunford Bridge, which is to the east, it was 58·56, being a trifle more than it was at the westerly side; at Penistone which is a very short distance off, it sank to 39·66, and at Sheffield it was down to 25·11 inches. That shows how much the conditions of the country and the physical features have to be taken into account when determining from known results in other places the probable amount of rain in places where you have not the advantage of rain gauges.

The next return shows the rainfall on the ridges between Loch Lomond and Loch Lubnaig.

Table No. 4.

Showing the Rainfall on the Ridges between Loch Lomond and Loch Lubnaig. Direction W.S.W. to E.N.E.

Years.	On easterly flanks of Ben Lomond. Elevation above O.D. 1,800 feet.	On Ridge between Loch Ard and Loch Katrine. Elevation above O.D. 1,500 feet.	On westerly flanks of Ben Ledi. Elevation above O.D. 1,500 feet.
	Inches.	Inches.	Inches.

1866	100·1	89·8	Incomplete.
1867	Incomplete.	Incomplete.	53·0

J. F. Bateman, Esq.

4 March 1868.

I have not with me a complete map of that part of the district, but I daresay this will be sufficient (*producing a map, and explaining the situation of the lochs and mountains upon it*). There is a second range of hills and a third range of hills beside the hills which lie away in Argyleshire. On the easterly flanks of Ben Lomond, taking the first year, at the point marked on the map at an elevation of about 1,800 feet, the rainfall is 109 inches in 1854; on the next ridge of hills between Loch Ard and Loch Katrine, and at an elevation of 1,500 feet, it is 67 inches; and on the next ridge of hills, the westerly flanks of Ben Ledi, the valley of Loch Katrine, and Loch Vennachar being between, it is 62 inches in round numbers. The rainfall at the head of Loch Katrine, at Glengyle, is as great as it is upon the flanks of Ben Lomond, above 100 inches in the year. Those are the returns which I promised the Commission with respect to that portion of my former evidence.

The next document which I hand in, according to promise, is a plan and section of the Loch Katrine aqueduct. The aqueduct commences at Loch Katrine, about one-third of the distance down, or about $2\frac{1}{2}$ miles from the upper end of the Loch; and it passes along in the direction indicated on the plan, crossing several great hills and valleys, and terminating, as far as the built aqueduct is concerned, at a place called Milngavie, which is in the valley of the Clyde, and from there it is carried by pipes to Glasgow.

6486. What is the distance?—About 27 miles to the Mugdock service reservoir, near Milngavie, and 35 miles altogether to Glasgow. The details show the various modes of construction of the aqueducts and tunnels, and will give a tolerably complete representation of the mode in which the Loch Katrine aqueduct is constructed, together with a plan and section (*delivering in the same*). In our first tunnel, which was under a hill, the summit of which at the point where we cross it is about 600 feet above the tunnel, we had 11 different shafts, four of which were between 450 and 500 feet deep, within about 110 or 120 yards of each other; it is in hard rock, mica slate very much twisted. We were about three years or rather more in driving that tunnel.

6487. (*Sir J. Thwaites.*) How long would it have taken you to have finished that tunnel without the assistance of those shafts which give you additional faces?—I should think 10 or 12 years; along Loch Chon we considered it very good work if we made four yards in a month, working night and day at one face. The Loch Katrine tunnel was not quite so hard a material as the material alongside Loch Chon.

6488. (*Chairman.*) What is the next point in which you have additional evidence to furnish to the Commission?—I was next requested to show the gathering grounds appropriated to the supply of water in Lancashire and Cheshire. I am sorry that I cannot hand it in to the Commission in quite so complete a condition as I would wish; but I have prepared a plan which begins as high as Lancaster (*delivering in the same*). The population of Lancaster is 14,457 according to the census of 1861. The extent of ground over which they have more or less a certain amount of right to take water is indicated by the blue line. That includes the land which is drained down to the compensation reservoir which they have to make, but the land which is specially appropriated to Lancaster is shown by the two patches of blue. The drainage ground of Fleetwood, Blackpool, Kirkham, Poulton, and Lytham is next upon my list, and the colour of the towns corresponds with that of the drainage area. Those five different places are supplied with water from a watershed in the valley of the Wyre, which is indicated by the yellow colour. They have a population of nearly 10,000, and their drainage ground is 1,100 acres. Preston has a population of 83,000, and they have a drainage ground appropriated to them for their own purposes almost entirely (for they have purchased the water rights there and do not give water compensation), which is indicated by the two purple patches, Preston being the purple circle and the two purple patches supplying them with water, and they are abundantly supplied. Burnley has a population of nearly 29,000, and they have 1,050 acres, as is shown upon the map. Then there is another place called the Nelson Local Board, and their drainage ground is given as 1,700 acres. I do not know what the Nelson Local Board is, but it includes a certain number of manufacturing villages to the north of Burnley. Then comes Blackburn, which is one of my own waterworks; the population is 63,000, and we have 2,860 acres of drainage ground, including the compensation water. We have just completed very considerable additions to the works, and there is an abundant supply of water. Darwen is a small manufacturing place of 14,000 people; they have nearly 1,000 acres of drainage ground marked yellow, and they are well supplied. Liverpool comes next. According to the census of 1861 they had a population of 444,000 persons, and they have 10,000 acres of drainage ground at Rivington, which is shown by a large patch of red, in addition to the wells which they have in Liverpool or close to Liverpool, from which a large quantity of water is taken for the supply of the town. Bolton has 70,000 inhabitants, and it has a very large amount of drainage ground by recent parliamentary enactment; the whole of the works not yet being carried out. The area is shown by a great extent of green, the whole of it not yet being appropriated; it is 12,220 acres in all, which is more than the land that is taken for Liverpool. Heywood is a place of about 13,000 inhabitants with a drainage ground of about 1,300 acres, shown by the brown patches. Oldham comes next, with a population of 72,000, and they get their water, including compensation water, from 2,565 acres, marked blue. Ashton and Staleybridge have a population of about 60,000; they get their water, including the compensation water, from an area of 1,776 acres (as is shown by the green patches). From a portion only of their land they have to give compensation water, as a part of it is free from compensation in kind. Then comes Wigan, with a population of nearly 38,000 and a drainage area of 2,200 acres, shown by the tract of purple land, on which there is only a small amount of rain, perhaps the lowest amount of rain and the worst drainage area of any of those which I have been alluding to. Bury has about 30,000 inhabitants and a drainage area of about 1,100 acres, also shown in purple. Then there are the towns of Haslingden and Rawtenstall, small manufacturing towns in the north of Lancashire, which have an abundant supply, the population being 15,000, and the drainage area over 2,000 acres. Then Manchester, with a population of about 500,000, has a drainage area of 19,000 acres, enclosed in a purple patch on the map, and they are abundantly supplied. There are some other reservoirs marked upon the map, the Rochdale Canal reservoirs, and the Leeds and Liverpool Canal reservoirs, which are marked purple. I have also marked Halifax as it came into the map, and it happened to be a waterworks which I am now constructing, and I have also shown the drainage ground of Dewsbury, in Yorkshire. I will leave the map with the Commission, and all the particulars are shown in this table which I will hand in (*delivering in the same*).

PARTICULARS of DRAINAGE AREAS appropriated to the Supply of Towns in Lancashire, with the Population of the Towns.

Name of Place.	Population according to Census of 1861.	Drainage Area appropriated to Water Supply.
		Acres.
Lancaster - - -	14,487	11,837
Fleetwood, Blackpool, and Lytham	9,896	1,116
Preston - - - -	82,985	3,380
Burnley - - - -	28,700	1,050
Nelson Local Board - -	—	1,700
Blackburn - - -	63,126	2,860
Darwen - - - -	14,327	966
Liverpool - - -	443,938	10,000
Bolton - - - -	70,395	12,220
Heywood - - - -	12,824	1,290
Oldham - - - -	72,333	2,565
Ashton and Staleybridge -	59,827	1,776
Wigan - - - -	37,658	2,200
Bury - - - -	30,397	1,100
Haslingden and Rawtenstall -	14,752	2,357
Manchester - - -	500,000	19,000
Leeds and Liverpool Canal Reservoirs - - - -	—	1,920
Rochdale Canal Reservoirs -	—	4,020
Halifax - - - -	80,000	7,536
Dewsbury, Batley, and Heckmondwike - - -	45,000	2,000

The produce of each 1,000 acres of the above drainage areas will vary from 1,250,000 to 2,250,000 gallons per day, out of which, in most cases, compensation to the streams has to be given, which is generally equal to about one-third of the total quantity capable of being collected.

In the map to which these tables refer the towns and their respective drainage grounds are shown in the same colours.

6489. Does the map show that the gathering ground and the district supplied are colored alike?—Yes. The towns with their respective drainage grounds are all in the same colour. The foot-note which I have already written is, "The produce of "each 1,000 acres of the above drainage areas will "vary from 1,250,000 to 2,250,000 gallons per day, "out of which, in most cases, compensation to the "streams has to be given, which is generally equal "to about one-third of the total quantity capable of "being collected." In the case of Wigan, for instance, which has the lowest amount of rainfall and the flattest land, the produce would not be more than 1,250,000 gallons for each 1,000 acres; whereas, in Manchester, and in Preston, and some of the higher parts, Halifax and others, the produce would be 2,250,000 for each 1,000 acres, out of which, in most cases, compensation to the streams has to be given, which is generally equal to about one-third of the total quantity capable of being collected.

6490. With regard to one or two of the towns in question, you stated that they were amply supplied with water, which observation had reference to the area of the gathering ground; what per-centage of acres to population do you calculate, taking the mean rainfall in those districts, would be equal to the requirements of the population?—That is very easily determined. Each 1,000 acres, if you collect 24 inches of rain from them and impound it for delivery, will give you 1,500,000 gallons of water per diem throughout the year.

6491. (*Colonel Harness.*) Is that calculation based upon results?—It is absolute, 24 inches of rain upon 1,000 acres collected amount to so much, and that divided by 365 days gives you 1,500,000 gallons per diem.

6492. Then it is a computation, not the result of experience?—It is as true as truth; it must be so. If you collect 24 inches of rain, that depth of water collected and impounded and delivered day by day will deliver for 365 days at the rate of 1,500,000 gallons per diem.

6493. But do they gather and store 24 inches of rain?—That is another question. They collect various quantities over the districts I have mentioned from about 18 inches to 36 inches; 24 inches would be less than the average collection from that district. If you take Preston, for instance, it has a population of 83,000 persons, and Preston is a town which does not use 20 gallons of water per head per diem, only 16 or 17; but if you take 20 gallons a day it wants 1,600,000 gallons daily, and the drainage area is 3,380 acres, and at 1,500,000 gallons, which they will much more than collect, because they will collect at least 30 inches of rain in the course of the year (and 24 inches of rain will give 1,500,000), the 3,000 acres will give you 4,500,000 gallons a day. They will have perhaps from 5,000,000 to 6,000,000 gallons at Preston for a population of less than 100,000, out of which they have to give a little compensation, I believe, but not much, because they have purchased nearly all the rights in the streams upon which their works are constructed. It happens that their streams are short streams before they get to the river Ribble, and they bought out those rights, and the river is a tidal river close to them, so that they have not been required to give compensation in water.

6494. (*Sir B. Phillips.*) What is the entire number of the population in the district included in your table?—About 1,500,000.

6495. (*Colonel Harness.*) Can you give the actual fact as to the rainfall and the quantity of water obtained for any of those districts?—Yes; I can give the quantity of water actually collected in Liverpool, in Manchester, in Halifax, and in several other places which are included in the table.

6496. (*Sir J. Thwaites.*) By "collected" do you mean for the purposes of distribution?—Yes, for the purposes of distribution after deducting waste. In Manchester we have an enormous quantity of waste water, and our works are not yet so completed as to enable us without some trouble to measure the quantity of water which runs to waste, although every now and then I do it for the purpose of getting accurate information. In a year, in which we had 45 inches of rain, we had collected or run to waste 33 inches, which shows a loss of 12 inches. In Liverpool they have collected on the average about 36 inches out of a rainfall of about 46 inches, that is taken from actual measurement, and calculated upon the average of several years; or if you take it for the year 1861, their rainfall was 46⅛ inches, and they collected 35¾, including what they impounded and what was run to waste. In 1862 the rainfall was 48½ inches, and they collected 40 inches. In 1863 the rainfall was 51 inches, and they collected 40¾ inches. In 1864 the rainfall was 39 inches, and they collected nearly 28 inches. I am not aware that I promised the Commission any further returns than those which I have now had the honour of handing in, and I believe they comprise all that the Commission were good enough to expect of me.

6497. (*Mr. Harrison.*) Before leaving the subject of the map which you have just put in, will you just state whether it does not clearly show that in the particular district of Lancashire to which it refers there is an abundant watershed which is still unoccupied for the purposes of the population?—The map itself will show that. I do not believe that there is one of the towns which I have named that may be said to have a deficient supply of water. Liverpool had a year or two ago, but they have got some extra powers which enable them to get over their present difficulties, and they are using a large quantity of water. Liverpool, perhaps, is the only one that I am aware of which may be said to have a deficient supply, and it was only owing to want of proper storage that they ran short two or three years ago. The map speaks for itself. The brown serpentine-looking colour shows the summit of the drainage ground east and west, and the coloured patches of appropriated ground are few and far between as compared with the whole extent of mountain country from which water might be collected.

6498. (*Sir J. Thwaites.*) You have put in a paper showing all the important towns in Lancashire, the smallest of which is Fleetwood, containing a

J. F. Bateman, Esq.

4 March 1868.

population of 9,896. How are all the minor towns, if they may be so described, or towns with populations less than that, supplied with water?—I think that the table contains most of the towns; but if we take the case of Manchester, Manchester has become the purveyor of water to all the surrounding small towns. Newton takes from it, Stockport a portion of its supply, Tyldesley, Worsley, and a great many other places of 3,000 and 4,000 inhabitants, all take their supply of water from Manchester. Manchester extends its pipes 20 miles from its service reservoirs for the supply of distant places. It also supplies Stretford and Bowdon and Altrincham, and, through the intervention of the Stockport waterworks, Alderley Edge. Again, Bolton supplies Farnworth, Hulton, and many other places; and so, through the great waterworks, nearly all the small places get a supply of water.

6499. (*Colonel Harness.*) Does the population attributed to Manchester in the table include those outlying places?—No, the population actually in Manchester and its surrounding district dependent upon the water supply is probably about 600,000, but as I could not give all those particulars I gave the census of the town itself. Manchester includes Salford.

6500. (*Chairman.*) You have taken Manchester as having a population, according to the census, of 500,000; I presume that is Manchester and Salford proper?—Yes.

6501. And the drainage area appropriated to its water supply you have taken at 19,000 acres; would those 19,000 acres represent the area which supplies Manchester and Salford alone with water, or would it include the other towns which Manchester furnishes?—It includes the other towns. The whole of the water which those 19,000 acres will give is something over 40,000,000 gallons per day; and when all our works are completed (we are still making reservoirs for holding the water), after giving compensation amounting on the average to about 13,000,000 or 14,000,000 gallons a day, we shall have for the supply of Manchester and the places dependent upon it at least 25,000,000 gallons a day.

6502. (*Sir J. Thwaites.*) What is the population of the county of Lancaster as compared with the population on that plan?—I could give that by referring to the census, but I have not it with me.

6503. Are there not a number of places of considerable importance in Lancashire not included in this list that are taking their supply from sources which are polluted by the discharge of the refuse of manufactories and sewage into the streams?—Very few, I think, if any. I think I know almost every town in Lancashire, and there are very few in the condition which you mention. There are some towns not included in the list which take their water from the new red sandstone on which they stand, and which, therefore, do not obtain it from gathering grounds; for instance, St. Helens and one or two places on the banks of the Mersey take their water by wells sunk into the new red sandstone, and they have no gathering ground. Ormskirk, again, is another place, and Southport is another place of the same sort. They get their water from the new red sandstone on which they are, or to which they are contiguous, and I think if you go over the whole of the towns in Lancashire I could almost answer for the condition of the water supply in every town, but I do not think there is one which obtains its supply from an impure source.

6504. Can you give us the population supplied with water taken from the new red sandstone?—I cannot do that. Liverpool takes nearly half its supply from the new red sandstone, that is 500,000 persons in round numbers to begin with, and I should think probably from 100,000 to 150,000 persons besides in Southport, Ormskirk, St. Helens, and one or two of the new places on the banks of the Mersey. I should think from 600,000 to 700,000 persons would take their supply wholly or in part from the new red sandstone.

6505. (*Sir B. Phillips.*) Did I correctly understand you to say that 1,000 acres would give 1,000,000 gallons of water?—From 1,250,000 to 2,250,000. 1,000 acres, from which 24 inches of rain could be collected and stored, would give you 1,500,000 gallons of water daily.

6506. Then the storage of the water at Manchester is considerably more than 24 inches?—Yes; we can collect certainly 33 inches in the driest year in Manchester.

6507. You have a drainage area of 19,000 acres, I think I understand you to say, and you have 40,000,000 gallons of water per day?—In Manchester each 1,000 acres would contribute upwards of 2,000,000 gallons of water per day, in fact 2,250,000.

6508. What is the rainfall there?—The rainfall, taking a dry year, would be something more than 40 inches, and taking the mean of three dry years we can collect 33 inches. The mean rainfall is a little under 50 inches.

6509. (*Chairman.*) Is it your opinion that Lancashire is at the present moment very well supplied with water?—Yes, it is; as a whole it is well supplied with water. Of course the population is so constantly increasing that they have to come frequently for extensions of works, but Manchester has a supply for a long period. Liverpool is using a great deal of water, and they are speaking of going to Bala Lake or getting an additional supply from the new red sandstone. Preston is abundantly supplied; Bolton is most abundantly supplied; Lancaster is abundantly supplied; Blackburn is well supplied, and all the places mentioned in that table, without exception, are well supplied for their present wants. Of course I do not say that in the course of the next 10 or 20 years they may not have to come to Parliament for further power; most likely they will.

6510. (*Mr. Harrison.*) If they are obliged to do so there is abundance of water to be got, is there not?—There is a great deal of water still to be got.

6511. (*Sir J. Thwaites.*) That additional power has reference, has it not, rather to the works than to the gathering ground?—And to the gathering ground also. They will have to go for more gathering ground. For instance, we shall have 25,000,000 gallons a day at command when our works are completed for the Manchester districts; but so soon as we approach anything like a demand upon us for 20,000,000 gallons we ought to go to Parliament for further gathering ground, because the construction of works takes such a time that we always ought to be at least five years ahead of the demand upon us.

6512. Apart from the statutory power you consider that you have ample gathering ground in Lancashire to supply its inhabitants with water?—I think so at present and for a long time to come.

6513. (*Chairman.*) Are there any statements which you made when you were formerly examined which you would desire to correct or explain?—There are. My survey of the country with reference to fixing the district and the reservoirs was made in the years 1860, 1861, and 1862, and at that time the railway in the Dulas Valley was not constructed. In the pamphlet which I wrote in 1865, and in the evidence which I subsequently gave with regard to the Dulas district, which is represented by this green patch to the south of that red reservoir on the map, I stated that that district had not been surveyed with reference to reservoirs, but that from a cursory examination of it it seemed as capable of affording sites as any other district. Between the time at which my survey was made and the time at which I wrote that pamphlet and gave evidence here, a railway was made through that valley, which destroyed the best sites for reservoirs; I find now that they could not be made there, or they could not be made certainly with the same advantage which I had previously considered. I was not aware of the fact of the railway being made, and therefore that was a misstatement which I made at the time I gave evidence before you.

6514. (*Sir J. Thwaites.*) If you are deprived of that valley now occupied by the railway, where do you propose to place your reservoirs?—There are sites in abundance. There is a very good site

which is marked upon the map, at a place called Babylon, and there is another large reservoir at the head of the Wye which can be taken into it, with an additional drainage ground; and there are various other sites for reservoirs probably not quite so favourably situated as they would have been if it had not been for the railway. There are two magnificent sites above Trefeglws, where reservoirs might be constructed at a level so as to receive the whole drainage water of this district, so that there are plenty of sites for making reservoirs.

Again, there was some statement made with reference to the lead workings, that there were more lead workings than I had given credit for, and that seems to have been so, inasmuch as some workings have been discontinued which were working at the time that I made my examination, and in other places others have commenced. I cannot do better than leave that question in the hands of Mr. Whalley, who knows the country perfectly, and has given evidence, and of Dr. Pole, who has examined the country, and can speak to the actual fact.

6515. How would you deal with those lead workings if they are more numerous and more extensive than you calculated upon?—They do not appear to be so. Some have been abandoned and others have been started, but they do not seem more numerous nor more extensive than they were.

6515*a*. You were under the impression when you gave your evidence upon the last occasion that some of those lead mines were out of working, and you have found that they are now in working?—There are some workings which have commenced in the interval between my examining the ground and publishing my pamphlet, and others have been discontinued; but I do not think that they are more numerous, or that there is a larger amount of lead working, taking the balance, than there was at the time when I examined the district. For instance, at the time I made my first survey, I abandoned that large portion of the river Severn proper, which is covered with green strokes on the map, because there were lead workings in it; but those lead workings have been discontinued, and the water is exceedingly good which comes from there; in fact, some of the best water and most abundant water that is available for collecting. In the place of the lead workings which have been discontinued other works have been commenced at other places, but it seems from the evidence which has been laid before you that no contamination of the water arises, that no lead is discovered, that the grosser particles may very easily be intercepted by subsiding reservoirs, as has been done, and that the finer parts of the material which is carried down from the washing are of real service to the water. The report of Dr. Frankland, which I had the privilege of reading, gives a most lucid, clear, and full description of all those circumstances. Therefore I prefer making no observation myself upon that subject, but would leave it to the information which has been obtained for the Commission by Mr. Pole, and to the chemical analyses of Dr. Frankland.

The next point, which seemed to be rather misunderstood, was, that I spoke of 1865 as the driest year. I spoke of it as the driest year with reference to the particular tables to which I was then alluding; and although it was almost the driest year of which we had any record, it was not absolutely so except with reference to the particular tables. But although it was not the driest year in point of rainfall, it was in most parts of the country the severest year with reference to the amount of water which was collected in all those districts where the supply of water depends very much upon springs. It was a more severe year than 1864, which was a drier year in point of amount of rainfall. In the Manchester waterworks we had a longer drought and a severer year in 1865 than we had in 1864. This diagram (*handing the same to the Commission*) represents the amount of storage at any one time in a certain number of years in the Manchester waterworks. At the commencement of 1864 the reservoirs were not as full as they were shortly after the commencement of the year 1865; they go down irregularly to a comparatively low level, and in the course of 1865 they go down to a still lower point and for a much longer period, and you will find over the whole of that diagram no drought so severe as the drought which occurred in 1865. The diagram does not represent the water falling in rain, but the water in store. In a great many of our reservoirs the greatest depth of water is about 80 feet, and at that time, in 1865, we had 1,012,000,000 gallons in store; at the lowest period, in 1866, we had 2,068,000,000 gallons in store; and in 1867 the lowest we came to was 2,384,000,000 gallons. I also have to correct a statement with reference to the drainage area, which is the only real inaccuracy of which I believe I have been guilty, and that has been a mistake of a figure. It was stated that the Thames drainage down to Kingston was erroneously stated, and it is so by an amount of 400,000 acres. Instead of being in round numbers 2,740,000, which I believe is the quantity given, it is really 2,340,000. I do not know how the mistake was made. I make it by a fresh calculation 2,382,400. Again, it was stated that I had over-estimated the drainage area of the Severn to Tewkesbury. Tewkesbury is below the junction with the river Avon, and the area, which I correctly stated in my evidence and in my pamphlet, includes the drainage of the Avon, which is about 628,000 acres. That added to the area which was stated by the other gentlemen will bring it up to the same figure as nearly as possible.

I believe there are no other statements that I wish to refer to except one as to the volume of water in the Thames in extreme drought, which seemed to be doubted. I did not gauge the Thames quite at its lowest point, but it was as nearly so as possible, and for several days it did not vary. It was measured on the 21st of September 1865. The river was measured in sections by wire ropes being strung tightly across the river at various places and distances marked upon them, and the depths were taken so as to indicate exactly the bottom of the river, and then by floats the velocity was taken in five or six different places by taking the time in which the floats went from one wire to the other. The velocity was not computed from the superficial velocity, but was actually ascertained by floats so adjusted that whilst one all but dragged upon the bottom and therefore showed the bottom velocity, another floated upon the surface and showed the surface velocity, or rather the one acted upon the other in quickening and retarding their respective paces. Gutta-percha is usually employed by me for gauging the velocity of streams. It is very nearly of the same specific gravity as water, being ·96 of water, and therefore it floats. A gutta-percha ball will float almost wholly immersed, so that the wind can have no effect upon it. The balls were so adjusted that one was heavier than the other and sunk to the bottom, but did not touch the bottom. Having ascertained the depth we adjusted it by a length of rope, which was attached to another ball, which floated upon the surface, and so we got the actual mean velocity. The place at which it was measured was just above the three pumping stations of the West Middlesex, the Grand Junction, and the Southwark and Vauxhall Companies at Hampton, and the total quantity of water was 308,720,000 gallons on that date. Nothing could have been more carefully done, and I am quite sure that that is as accurate a measurement as ever was taken of the quantity of water which is discharged in the Thames.

6516. (*Sir J. Thwaites.*) I presume careful sections of the river were made at that part where you gauged it?—Yes.

6517. You make the minimum flow considerably less than Mr. Simpson?—I know I do; but I do not think that it was ever measured with such accuracy before, or that he did it in the same way. But Mr. Simpson takes his supply from the river at Thames Ditton, at a point which is below the river Mole, and therefore he gets the river Mole in addition.

J. F. Bateman, Esq.

4 March 1868.

6518. Did not Mr. Hawksley give evidence very much to the same effect, that the quantity was about 350,000,000?—I do not know whether Mr. Hawksley himself measured it, but Mr. Simpson's measurements are at Thames Ditton and include the Mole, which gives a very inconsiderable quantity in dry weather; but some additional quantity of water comes in between the two points of measurement, and therefore the quantity ought to be larger.

6519. Did you ascertain the mean flow?—No. I was only anxious to ascertain the minimum, the mean flow you can hardly possibly get.

6520. (*Mr. Prestwich.*) Do you think that the Mole would account for that difference?—No, it would not fully account for the difference.

6521. (*Sir J. Thwaites.*) During how many days was this gauging made?—The actual velocities were taken in one day; the preparation took several days in getting all the lines across, and all the sections; but the velocities were all taken in one day. Wire ropes were put across and staked, and the points marked and levels taken, and so on; then the velocities would be all taken in one day, so as to be all exact on that one day. I may mention that in large rivers and open watercourses I have worked constantly with Eytelwein's rule, and I have always found it as nearly as possible correct; and Du Buat's rule also in open watercourses, where we have a tolerably uniform section, is as nearly as possible absolutely correct.

6522. Supposing you had a very high wind, would not that have mastered the retarding influence at the bottom?—We should not have ventured to have taken the observations in a high wind; it was a calm day, otherwise we should not have ventured to run the risk of the possibility of error. The lower ball would not be influeuced by the wind, but the upper ball might be influenced by it.

6523. (*Chairman.*) Is there any other statement which you wish to correct?—I think there is no other which occurs to me.

6524. With regard to the rain returns that is the next point, is it not, to which you wish to call the attention of the Commission?—Yes. I am very anxious that the Commission should bear with me a little while I explain all that as clearly as I can. I ventured to make the statements which I did, not at hazard, but after a very careful consideration of the circumstances of the country and the information which I had been able to collect, that the rain upon this portion of Wales would be as great as in Cumberland in similar localities, and in the district surrounding Loch Katrine. I stated that the rain would be on an average from 70 to 80 inches, that 60 inches would be the rain on the average of two or three consecutive dry years, and that we might safely depend in such years upon collecting 48 inches. I did not take 48 inches in estimating the quantity of water which we could collect, but, if you remember, I took 36 inches, which gave from the storage which we have 220,000,000 gallons of water per diem, and then by adding about half a foot a second for the quantity of spring water which would be yielded on an average during a long drought, equal to 30,000,000 gallons a day, we should have a supply for 120 days of 250,000,000 gallons beyond doubt. I am anxious to show the Commission that every one of those statements was almost absolutely correct. If you refer to the evidence, I took, if you remember, nine gauges in Cumberland and Westmoreland, which I selected for the purpose of comparing as nearly as I could with nine gauges under as nearly similar circumstances as I could select them in the Welsh district—gauges which had been kept independently of any of my own; and it showed that in each district those gauges were within less than an inch the same. The advantage in point of position I considered to be with the Cumberland gauges as likely to show a larger amount of rain than those in Wales; but it so happened that in the year 1865, which was the year I took, the rain was in both cases on an average throughout 59 inches. Last year, 1867, I have taken the returns out for both the gauges in Wales and in Cumberland, which I then selected, and I find that the rain last year in Cumberland was two per cent. less than the mean rain of 22 years in the Cumberland district, taking Mr. Symons's standard gauges which are at Seathwaite at the head of Borrodale, the How in Troutbeck and Keswick, where observations have been continued, as he gave evidence last year, for 22 years, and therefore he determined by reference to the mean of that lengthened period whether any particular year was above or below an average; taking the same mode of proceeding, and taking the same gauges, I found that the Cumberland gauges were two per cent. below the mean rain of 22 years. In the Welsh gauges I have to add 10 per cent., because the only gauge which has been continued for any period, the only one which has any reference to this mountain range is, the Rhyader gauge. The rain last year was 10·18 per cent. less than the mean of 10 years during which this gauge has been kept. Therefore I have to add to the returns in Wales 10 per cent. to bring them up to the mean rain, that is to say, to what would be the rainfall at those particular gauges if it had been a year of mean rainfall. Having premised that in order to show the Commission the way in which the thing has been worked out, I will show you that the mean rainfall in Cumberland of those nine gauges, which are Keswick, Scawfell Pike, Derwent Island, Great End, Brant Rigg, Esk Hawse, Ambleside, Patterdale Hall, and Wasdale Head, varying in height from 250 to 3,200 feet above the level of the sea, was 72·77 inches, and adding two per cent. in order to bring it up to what would be the year of mean rainfall it comes to 74·27 inches. And as to the actual rain in Wales, the mean of the rainfall at Dolgelly, Trawsfynnyd which is above Dolgelly, Festiniog, Rhiwbryfdir, Beddgelert, Bettws-y-coed, Llanberis, Rhayader, and Llanidloes, Llanidloes being a place within the district, at heights varying from 70 feet to 1,140 feet above the level of the sea, and therefore very much inferior in height to the Cumberland gauges, the actual rain upon the average of all those was 67·92 inches, and adding 10 per cent. in order to bring them up to a year of mean rainfall, they came to 74·71 inches against 74·27 inches. I also stated that the rain in my own district, if I may call it so, would be as great as the rain of the district selected by Mr. Hemans and Mr. Hassard, or nearly so. Eight gauges were put down in that district under the care of Mr. Symons for the purpose of determining the amount of rain, and the actual rain upon the average of those eight places is 75·77, and adding two per cent. in order to bring it up to the mean rainfall it would be 77·27. Then, taking six gauges in my own district compared with eight in the other, the actual rain last year, 1867, at the gauges in Wales over the whole district proposed to be appropriated was 67·57, and adding 10 per cent. to that in order to bring them up to a year of mean rainfall, it comes to 74·32 against 77·27 in the Ulleswater district. I have already stated that I believe that the rain in the Welsh district would be as great as the rain in the Loch Katrine district. I find that some of the mountain gauges on Loch Katrine have been discontinued from the difficulty of attending to them, and the manner in which they are frozen, and so on, and therefore I am obliged to make a selection of those which as nearly as possible represent the mean rainfall; five of them may be taken to do so, and the mean rainfall in 1867 of those five gauges was 72·64 inches. Those places are Loch Dhu, Loch Drunkie, Loch Venachar, the hill above the Loch Katrine tunnel, and Glengyle, Glengyle being at the head of Loch Katrine, and showing as large or larger an amount of rain, although it is a valley gauge, as falls upon the high lands. The mean rain of those same gauges, taken over periods varying from seven to 14 years, is 77·34 inches. Therefore this year, 1867, was about seven per cent. less than the mean rainfall. Now taking the mean rainfall you have this state of things, that the nine gauges in Cumberland which I took for the purpose of determining the question before I

had any other facts before me, show a rainfall of 74¼ inches, whereas the Welsh gauges, which I took as corresponding gauges, show a rainfall of 74¾ inches; the gauges on the Ullswater district proposed to be taken for London show a rainfall of 77¼ inches. The gauges of my own Welsh district show a rainfall of 74¾ inches, and the rainfall of the hills round Loch Katrine, in Scotland, appears to be 77⅓. They are all between 70 and 80 inches, which was the statement I made with reference to that subject. Perhaps the Commission will allow me to hand in some tables which I have prepared, showing the rainfall in the Welsh district upon which my calculations are founded.

TABLE showing the RAINFALL in the District in NORTH WALES proposed to be appropriated for the Supply of the Metropolis, from October 1st, 1866, to December 31st, 1867.

Months.	No. 1. S.W. of Llanidloes. Elevation above O.D. 950 feet.	No. 2. Head of the River Clwyedog. Elevation above O.D. 1,300 feet.	No. 3. In the Valley at Carno. Elevation 550 feet above O.D.	No. 4. On hills at Can Office. Elevation above O.D. 1,100 feet.	No. 5. In the Valley at Llanwddyn. Elevation above O.D. 720 feet.	No. 6. On Hills at the head of the River Vyrnwy. Elevation above O.D. 2,000 feet.

J. F. Bateman, Esq.

4 March 1868.

Vyrnwy and Banw District.

Llanwddyn or Vyrnwy District.—Drainage area, 22,352 acres.

Gauges Nos. 5 and 6 are situated in this district and represent the rainfall on the lower and higher portions of the drainage ground respectively, the lower portion forming one-third and the higher portion two-thirds of the whole.

The mean rainfall of the district will therefore be the mean between the rainfall at gauge No. 5, and twice the rainfall at gauge No. 6, as follows:—

	Actual Rain for the 12 months ending Sept. 31, 1867.	Approximate Mean Rainfall.	Mean of the District.
Gauge No. 5; elevation 720 ft.	67·4	74·14	74·14
Gauge No. 6; elevation 2,000 ft.	81·7	89·87	89·87 89·87 ÷3 = 84·63 ins.

Banw District.—Drainage area, 44,028 acres.

The only guage in this district is No. 4, on the hill above Can Office. Gauge No. 6 is, however, within two miles of the summit of the drainage ground, and it will represent the rainfall on the higher portion which forms one-fourth of the drainage area. Gauge No. 4 will represent the middle level of the district, which forms one-half of the whole, and on the remaining one-fourth of the drainage area, being the lower portion, a less rainfall will obtain, and it has been assumed that gauge No. 1, above Llanidloes, will approximately represent the rainfall of this level.

The mean rainfall of this district is determined as follows:—

	Elevation above the Sea.	Actual Rain for the 12 months ending Decr. 31, 1867.	Approximate Mean Rainfall.	Mean of the District.
	Feet.	Ins.	Ins.	Ins.
Gauge No. 4	1,100	58·9	64·79	64·79

Summary for Vyrnwy and Banw District.

	Drainage Area.	Mean of the District.
Llanwddyn or Vyrnwy District	22,352 acres	84·63 ins.
Banw District - - -	44,028 acres.	68·75 ins.
Total - - -	66,380	Mean 74·09 ins.

River Severn District.

River Carno District.—Drainage 17,289 acres.

The only gauge in this district is No. 3, in the valley at Carno. For the higher level of the drainage ground, which forms one half of the whole, it has been assumed that a mean of gauge No. 3 and of gauge No. 2, at the head of the river Clwyedog, about 3½ miles distant, will represent the rainfall. For the lower level, which forms the other half of the drainage area, the gauge No. 3 will represent the rainfall.

The mean rainfall of this district is therefore as follows:—

	Elevation above the Sea.	Actual Rainfall for the 12 months ending Decr. 31, 1867.	Approximate Mean Rainfall.	Mean of the District.
	Feet.	Ins.	Ins.	Ins.
Gauge No. 3	550	65·8	72·38	72·38 93·17
				165·55
Do. „ 2	1,300	84·7	93·17	82·775 72·38 ÷2 = 77·57 Ins.

Rivers Dulas, Twlch, and Afon Brochan District.—Drainage area, 15,139 acres.

The only gauge in this district is No. 1 in the valley to the S.W. of Llanidloes. The higher portion of the district, forming one half of the whole, is similarly circumstanced to the higher portion of the Carno district, and for this area the same mean rainfall, 82·775 ins., will apply. For the lower portion, which forms the remainder of the district, the gauge No. 1 will represent the rainfall.

The mean rainfall of this district will therefore be as follows:—

	Elevation above the Sea.	Actual Rainfall for the 12 months ending Decr. 31, 1867.	Approximate Mean Rainfall.	Mean of the District.
	Feet.	Ins.	Ins.	Ins.
Gauge No. 1	950	46·9	51·59	51·59 82·775 ÷2 = 67·18 Ins.

Rivers Clwyedog, Tarannon, and Ceryst District.—Drainage area, 31,764 acres.

The rain gauge in this district is situated at the head of the river Clwyedog, and this gauge will represent the rainfall on the highest level of the drainage area, which forms one-third of the whole. For the lower range of hills which flank the drainage to the north and south, and are similarly situated to the hill portion of the Carno district, the mean rainfall of that district will apply. The rainfall on the lower level of the drainage ground and the valleys will be represented by gauge No. 1. The three levels are approximately equal in area.

The mean rainfall of the district will therefore be as follows:—

	Elevation above the Sea.	Actual Rainfall for the 12 months ending Decr. 31, 1867.	Approximate Mean Rainfall.	Mean of the District.
	Feet.	Ins.	Ins.	Ins.
Gauge No. 2 -	1,300	84·7	93·17	93·17
Gauge No. 1 -	950	46·9	51·59	51·59 ÷3 = 75·51 Ins.
Hill gauge for Carno district, mean of Nos. 2 and 3	- -	- -	82·775	82·775

I am obliged, reluctantly, to make observations upon some evidence which was given with regard to what was likely to be the rainfall, and what was likely to be the produce, because upon that of course very much depends, and I am obliged to refer to the evidence of Mr. Symons. Mr. Symons gave evidence before the Commission on two days. He grounded the results which he arrived at on the observations that I was enabled to give him of three

complete months, the last months of 1866, and he compared the rainfall with the rainfall in the Ullswater district for the same period. The rain in the Ullswater district was 31 inches, the rain in the Welsh district was 19 inches, and he came to the conclusion that it was a rule-of-three question. The mean annual rainfall he reduced for the Cumberland district to 77 inches, and in that respect I must give him credit for being very near the truth, because the mean rainfall of those gauges was 77¼ inches, therefore he was remarkably correct in deducing that rainfall. And he put it in this way: as 31 inches in Cumberland were to 19 inches in Wales, so 77 inches would be to the gross amount of rain in Wales, that is to say, to 47 inches as the average rain in Wales. But he omitted to draw your attention to the effect of a statement that he made that in the lake district the three months rain was 24 per cent. above the average, and in Wales it was only 17 per cent., taking Lampeter, Rhayader, and Hawarden as his guides. Then he ought to have deducted 24 per cent. from 31 inches, and 17 per cent. from 19 inches, before he was able to put this equation as a rule of three question. 31 inches minus 24 per cent. is 23½, and 19 inches minus 17 per cent. is 16 inches, so that it should have stood thus: as 23½ are to 16 so are 77 to the result, which in that way would be 52 inches instead of 47 inches. But why does he take Lampeter and Hawarden? He might as well take London and Paris; they are quite away from the mountain range, and they cannot be supposed to indicate the rain in the hill district any more than Sowerby Bridge, on the eastern foot of the backbone of England, can indicate the rain upon the tops of the hills or the ratio. If he took Rhayader, which I have not the slightest objection to his doing, it being very near to my district, the Rhayader gauge was only 13 per cent. minus, on the average of nine years I think it was, so that from 19 inches only 13 per cent. should be deducted, making 16⅓, and it then would read thus: as 23½ inches are to 77, so 16⅓ would be to the result, which would be 54. So that taking his own figures properly used, the result would have been, according to his figures, 54 inches instead of 47 inches. As he has taken it, Mr. Symons said that he thought the thing was wrong, although he could not see where it was wrong, but he believed there was more rain. I have merely taken the Commission through this calculation for the purpose of showing that his own figures properly handled produce a very different result from that which he laid before you. I may now mention to you what the actual state of things is. After having carefully considered the whole question, and appearing again before the Commission, Mr. Symons came to this conclusion, that the mean rain would be 60 inches, but considering special circumstances he assumed it to be 55 or 56 inches. Now the special circumstances, as far as I understand his evidence, are, that five-sixths of the gathering ground would be represented by the valley gauges, being low land, and that only one-sixth would be high land and fairly represented by the high gauges. He is entirely wrong there, as I have shown in the preceding tables. The gauges were put down for the purpose of representing as nearly as they could the average amount of rain, and by carefully considering the altitudes of the various districts and appropriating the amount of rain according to the altitude, the result is that the rain for the year ending 1867 in the Welsh district, corrected for mean rainfall, being 74·32 inches, and the mean rain according to elevation of ground being 74·58, the difference is less than half an inch, so that the rain-gauges which I put down do exactly what they were intended to do—that is to say, they represent the mean rain over the whole district. Mr. Symons then gave you a table of what he considered to be the "*true mean*," as he called it, of the district under consideration, and he gave the rain in the valley south-west of Llanidloes as 48·39, whereas the actual rain was 50·7. On the hills above Llanidloes he gave the true mean 80·32; the actual rain was 85·1. In the valley at Carno he calculated that it would be 40·32; it was 63·8. On the hills near Can Office he estimated the rain at 59·13; it was 62·4. In the valley at Llanwddyn he estimated 52·68; it was 67·7. On the hills above Llanwddyn he estimated the rain at 80; it was 86·1. The mean of his estimated result was 60·14; the actual state of things was 69·3. That was for the year not ending December 31st, 1867, but September 30th, 1867, which included the three months to which he had specially directed his attention; the rain of that period was only three per cent. less than the mean rain, and therefore I have to add to that amount three per cent., which brings up the rain corrected in that way to 71·38, instead of 60·14. The year ending the 31st December, 1867, shows a rainfall, corrected so as to bring it to a mean rainfall, of 74·32, the mean of the two being 72·85, in round numbers 73 inches. I have laboured this perhaps rather more than is interesting to the Commission, but I was anxious to show that the figures which I have given you are really figures which I am now able to lay before you with confidence. These are actual results corrected in the way I have shown you, and I was quite justified in taking the average rain at an amount of between 70 and 80 inches, and the minimum rain of three consecutive dry years at 60 inches. Adopting the rule which has been stated before you, and which, although it is not universally true, yet is sufficiently near the truth to be adopted, that the mean of three consecutive dry years is one-sixth less than the average rainfall, thus if from 73 inches (if you take the year ending the 30th of September), or 74 (if you take it as ending the 31st of December), you deduct one-sixth, that leaves you 61 or 62 inches, according as you take the one or the other, as the mean of three consecutive dry years. If you deduct from that 12 inches as the amount of loss by absorption and evaporation, which is a full amount in this district, you have 49 or 50 inches, as you take the one or the other year, as the residual quantity of water which you may collect in reservoirs in the driest years. I have only taken it for the purpose of calculation before you at 36 inches, plus springs, which brings it to about 40 inches. I need not pursue that further, but I must now give you the amount of loss which I have stated at 12 inches. I will give it from some tables which give the annual loss in various places. In Liverpool I have already stated the result of 1861, 1862, 1863, 1864, and 1865 in answer to a question of Sir John Thwaites, showing that the mean loss there is about 10 inches out of a rainfall of some 47 inches. The average rainfall of the five years taken together was 46¼, and the amount collected was 36·10, therefore the loss was a trifle more than 10 inches in the year, and that is from a small rainfall. In Sheffield, where some years ago they had reservoirs so large that they could not fill them, and therefore they made the best possible gauge basin in the world, and where the rain is received from a tract of flat moor land, they had an average amount, over a great number of years, of 39½ inches, and they collected 25 inches from those flat-topped hills which are covered with peat, and which are therefore liable to considerable loss from absorption and evaporation, showing a loss of 14½ inches. At the Gorbals waterworks, which now form part of the Glasgow waterworks, the quantity of rain and the amount of loss were very accurately observed for many years, and the mean loss on a considerable number of years was 10¼ inches. I could mention others, but those are the most certain returns that I could refer you to. I may, perhaps, mention one other return, which is the case of Newcastle-upon-Tyne, the Whittledean waterworks, where the rainfall is excessively small, and where the drainage ground is very flat and highly cultivated, and therefore the loss may be considered to be likely to be very much. In the year 1850 they had only 17⅔ inches, and they got only 6⅓ into their reservoirs, their loss being 11·13. In 1851 they had 21⅓ inches of rainfall; they collected 8 inches, and the loss was 13⅓. Therefore upon all

J. F. Bateman, Esq.

4 March 1868.

those returns I think I am justified in saying that 12 inches is more than enough to deduct, so that I hope I have made good my ground that the rainfall is as much as I represented, and that we should be certainly able to collect more than 36 inches, that we might safely calculate upon 48 inches, and that therefore all the calculations which have been made by other parties which contravene these have been made without sufficient information and are erroneous.

6525. (*Mr. Prestwich.*) You have given us the mean of the three driest years; what do you estimate to be the rainfall of the driest year?—I should think that the rainfall of the driest year would probably be about 50 inches or a little more.

6526. Do you state that from recent gaugings that you have made in the driest year?—I cannot decide the driest year. The driest year will be less than the mean of three dry years, and I have taken the mean of three dry years, for where we have large storage reservoirs we do not require to take the driest year, because we have a stock in store which will help out a dry year; therefore if we get three dry years together we take the mean of three dry years, and if we only get two dry years together we take the mean of two dry years.

6527. For what period have you storage?—If we provide storage, say for 120 days, and we start with our reservoirs full, that is just one-third of the year, and if we calculate on obtaining 36 inches in the year, the water in store would be equal to 12 inches of rain. Therefore we can add 12 inches throughout the whole year to the minimum year, or if it goes on for two years we can add 6 inches, or if it goes on for three years we can add 4 inches.

6528. Should you not take the minimum year *plus* that 12 inches?—No, there would be no use in reservoirs if reservoirs are not to help out periods of drought. You will understand that if we have storage which is equal to 120 days' supply that is equal to one-third of the year. If we calculate with reference to collecting 36 inches that we shall have 12 inches store, and if you come to a year which is 12 inches below what we can calculate upon, our store will just meet that. If it has to last us two years there are 6 inches, and if there are three consecutive dry years, and you calculate upon your reservoir lasting three years, you have 4 inches in store to go to help out deficient years.

6529. You say you calculate upon a storage equal to 120 days?—Yes, that certainly should be the quantity, or 140 days for a smaller quantity.

6530. That 120 days' storage being equal to a rainfall of 12 inches?—Yes, over the year.

6531. Is not that the quantity which you have to add on to a minimum year?—It would be, but I am lowering it on purpose. I have taken only 36 when I might have taken 48. Supposing I had taken 36 inches, and 36 was the mean of two dry years, and in one year there happened to be only 24 inches collected, I have 12 inches in store. I should get my 36 inches discharged, and if I should be empty at the end of the year I should start the next year with an empty reservoir. If I have two years to provide for, and calculate upon the reservoir working for two years, and I have 36 inches, and that is all the rain I can get on the average, and I then have a fall of rain of 30 inches only, I could discharge that 30 inches and 6 inches out of my 12 inches of store, and make it up to the 36 inches, and I should then start with the reservoir just half full, with 6 inches in store towards another dry year,

6532. Then do I understand you rightly that the total amount of your storage would not exceed 12 inches of rainfall?—Yes; the total amount of my storage is just 12 inches in depth over the whole surface.

6533. Supposing we were at the beginning of the driest year, that is the total surplus which you could carry over from the previous year to make up the deficient supply of the driest year?—That is so. I should never be short, inasmuch as I have 48 inches upon the average—certainly more than 40 inches after deducting for loss in the driest year. I should never exhaust my store. I should always have water in store.

6534. It would seem, then, that the surplus quantity of 12 inches must be added to the driest year that could possibly occur?—Yes; but the driest year that may possibly occur in that district would exceed 40 inches after making deductions; 60 inches upon the mean of three dry years might be said to represent perhaps 52 or 53 inches in an extreme year, or something like that. Deduct 12 inches from that, and you have 40 or 41 inches, and as you only calculate upon discharging 36 inches, you have four or five inches to the good on that year, or if you discharge the whole 40 or 41 inches, supposing you have none running to waste by floods, you have just equal to the demand, and it leaves you with your reservoir full at the end of the year.

6535. It all rests, does it not, upon what may be the minimum rainfall?—Yes. I think I have stated sufficient to show that the minimum rainfall is not half of the average, but perhaps two-thirds of the average. The minimum rainfall of 75, or in round numbers 74 inches, would be certainly over 50 inches. I have had a table just handed to me of the rainfall in the Loch Katrine district, and there is one case in which the rain has been gauged for 15 years, during which time there were two very dry years and some wet ones, and there I find the mean rainfall was 59 inches, and the minimum was in 1855 39 inches; that is just two-thirds; if it was 40 inches and 60 inches it would be exactly two-thirds. I will take another year, a low country gauge for the same number of years. The mean rainfall was nearly 54, and the minimum rainfall was nearly 35; that is not two-thirds. Then I will take the rain gauge at the head of the Duchray valley, which has a very large rainfall, amounting to 114 and 117 in some years, and some years very much less; there the mean rainfall was 90·6 and the minimum rainfall in 15 years was 67·2, that is more than two-thirds. In 22 years in the Cumberland district (this is from Mr. Symons's tables) the mean rainfall was 58·53 and the minimum in 1855, which was also the minimum in the table which I have given you, was 37·40, that is rather more than two-thirds. There seems to be no case in which it falls lower than two-thirds, and hardly a case in which it does fall to two-thirds; so that the minimum rainfall here may be said to be 50 inches out of 74 inches, which is the mean rainfall.

6536. Those two districts are districts in which rain-gauges have been carried on in one case 15 years, and in the other 22 years. How long a period have your experiments extended over in the Welsh district?—Taking the Rhayader gauge 10 years.

7537. All those districts are districts of extreme rainfall, but do you not suppose that you would be liable in the Welsh district to as great extremes as occur in the Scotch and in the Cumberland districts?—Just so; and the extreme seems to be as nearly as possible in the Cumberland district two-thirds, and in the Loch Katrine district two-thirds also; that is to say, the minimum rainfall is two-thirds of the mean rainfall.

6538. Are there not, in both those districts, instances in which the rainfall fell below 40 inches in particularly dry years?—No, that was at particular gauges (it was not the mean of all the gauges), and those happened to be low-country gauges; the mean is two-thirds. If you take Seathwaite the driest year was 88 inches. You cannot determine what their particular amount would be, but you can determine the proportion which a minimum year bears to an average year. If the average rainfall is 75, and you take two-thirds, that would be 50; if the average rainfall be 45 two-thirds would be 30; if it be 90 two-thirds would be 60. If you take the Glasgow table, which represents the rainfall of the Loch Katrine district, and the tables of the rain at the places which Mr. Symons took for his

standard returns, in both those cases the minimum is as nearly as possible two-thirds of the mean rainfall.

6539. Is not that an estimated quantity?—No, not an estimated quantity; it is the actual quantity. In the Cumberland district it bears the proportion of 37·40 to 58·53, and in the Loch Katrine case it bears the proportion of 67·2 to 90·6; and in another case which I gave you it bears the proportion of 39 to 59. That is almost exactly two-thirds. *J. F. Bateman, Esq.* 4 March 1868.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 5th March 1868.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS, C.B.	JOSEPH PRESTWICH, Esq.

JOHN FREDERIC BATEMAN, Esq., further examined. *J. F. Bateman, Esq.* 5 March 1868.

6540. (*Sir J. Thwaites.*) Before proceeding to the next subject, permit me to ask you a question with respect to the gauging of the Thames at the point indicated on the sections which you have handed in. You have adopted a very ingenious and certainly a very simple mode of ascertaining the mean velocity of the stream, and probably something of the same kind was used by Mr. Foster in 1851, though not with the same accuracy as now; what I want to know is, whether in adopting this principle of gauging it is the recognized formula used by engineers, because they are generally careful in thoroughly testing any new principle in its application, especially to large streams. You took, I think, seven sections?—Yes.

6541. And the velocity of the stream was ascertained from one section to the other?—Yes, the mean of all the observations upon the sectional area to which those particular observations applied.

6542. Did you apply your floats to the sides of the stream as well as the centre?—Yes.

6543. I understand that the principle which you adopted was to submerge a ball within such a distance of the bottom as not to come in contact with any substance, and to submerge another ball to the extent, probably, of seven-eighths of its bulk, near the surface?—Yes.

6544. And those two balls were tied together?—Yes.

6545. And the friction at the bottom of the river impeding the current of course kept a check upon the upper ball?—Yes.

6546. And by that means you obtain what you consider to be a correct mean velocity of the stream?—Yes.

6547. After those gaugings were made did you test on the same sections the formulæ generally used by engineers to test the correctness of this principle?—I do not think that was done. This mode of ascertaining the mean velocity is much older than I am. I have adopted it for the last 25 or 30 years, and I have every reason to believe by other experiments made expressly for the purpose of determining what formulæ we can found upon, and what we cannot, that it represents, as nearly as we can determine it, the results of the most careful formulæ deduced by other people. But you will see that except in some such way the velocity at the bottom can never be ascertained.

6548. I only want to know the fact whether you tested it by any other formulæ on the same ground?—Not on the same ground, but I have tested that mode of gauging frequently in other places where I have had the means of making every possible observation. When I laid out the Manchester waterworks, I constructed the works in many parts with special reference to taking such observations as would determine a great many points which were somewhat in doubt, and I then tested all the calculations of almost everybody, upon the watercourses in the Manchester waterworks, where we had every facility for doing it.

6549. And what has been the per-centage of error, as compared with the usual formulæ?—One has to use our formulæ with some amount of caution, because the formulæ have been determined from experiments made under certain conditions, and our experience and practice enable us to determine the conditions which are either more favourable or less favourable to the truth of the formulæ. I will give, for instance, the case of a common formula for calculating the quantity of water discharged over a weir. The ordinary formula is to extract the square root of the depth of the water in feet flowing over the weir, and take two-thirds of that and multiply it by 5·1. Through an aperture which is wholly submerged you multiply the area by the depth upon the centre of the aperture, and multiply the square root of that by 5·1, but according to the character of the opening the proper co-efficient will vary from 5 or 5·1 to nearly 8. In the gauging observations made on the Manchester waterworks for the express purpose of ascertaining how that was, a certain gauge basin was constructed, and in that I made three apertures 6 feet long and 6 inches deep, all of exactly the same dimensions and under the same head. Then I received the water discharged through the aperture into a large vessel made expressly for the purpose, a square tank, so as to determine the exact quantity of water flowing into the vessel in a given time. Then I reduced the proper formulæ from the quantity of water which was received and therefore discharged through those various openings, and the co-efficient of discharge varied according to the three classes of openings (I will explain this directly) from 5·6 to 7·76. A velocity of 8·04 is the full velocity which can be acquired by a falling body falling 1 foot, and through one particular opening the discharge was nearly equal to the velocity due to the whole depth through which the body would have fallen. (*The witness described the experiment upon a drawing.*) In all those cases one has to regulate very much the application of the formulæ according to our knowledge and experience.

6550. In dealing with large streams no doubt the difficulty is increased?—Yes, and that was the reason especially which made me reject all formulæ and ascertain upon the spot what was the actual velocity, and I could not ascertain what was the actual velocity in a more perfect way I believe than the way which I adopted. Therefore that is independent of all formulæ, and if the formulæ do not agree with it the formulæ are incorrect.

6551. I am induced to put the question to you, because Mr. Simpson having made a very careful gauging of the velocity of the stream, or a very accurate section having been made by him from time to time, the serious difference between you and Mr. Simpson upon that point gave rise to some anxiety in one's mind as to whether Mr. Simpson was wrong or you were wrong, and whether it might be due to the mode of gauging on one side or the other?—I do not pretend to say that Mr. Simpson is wrong, but the

J. F. Bateman, Esq.

4 March 1868.

actual results are worked out there. I may observe that I was wrong in stating as I did yesterday that 1865 was the driest year in the Lea and the Thames. It appears that 1864 was the driest year, but it was the excessive drought to which we were subjected in the north of England which led me to ascertain what quantity of water was in the Thames in that year. I believe 1864 was really a severer year, and I have before me the particulars, not so much of the Thames as of the river Lea.

6552. Would not the severity of the drought of 1864 manifest itself in the discharge of 1865?—Most likely it would, but I see that the quantity of rain which fell in the two or three months immediately preceding September 1865 was very considerable. Of course in a chalk district like the upper part of the Thames basin the water is a long time percolating and discharging, and the rain of the autumn influences the spring of the next year probably.

6553. (*Colonel Harness.*) The plan which you adopted gave you, did it not, six whole values of discharge, there being six intervals?—Yes.

6554. Do you remember the difference between the greatest and the least?—I do not. I may mention that the gentleman who took these gaugings in the Thames, who now is in America, and the young gentleman who assisted him in this operation, and who is now in Glasgow, came to this operation fresh from having gauged the river Shannon at various places for the purpose of an inquiry for government, and they were thoroughly up to everything that was required.

6555. (*Chairman.*) Taking you back for a moment to the district which you were upon yesterday, namely, Manchester, Blackburn, Burnley, and various other places as to which you gave us the amount of water which they got and their gathering grounds, would it be possible before we leave that part of the subject for you to give the Commission any information with regard to Sheffield, which is not very far from that district?—Sheffield has recently acquired an enormous amount of gathering ground. By an Act of Parliament passed only last session it has got command over an extravagant amount of ground for the supply of Sheffield, namely, 36,000 acres, which is as nearly as possible twice the acreage which Manchester has acquired. The rain is not quite so much on the east as it is on the west; but if you take it at 24 inches, which is about the available produce in the Sheffield district, or perhaps rather more in the district which they have last gone to, it will give 54,000,000 gallons of water a day, and if they give one-third of that as compensation they will still have something like 40,000,000 gallons a day at the command of Sheffield and the surrounding district.

6556. Are they constructing any very large works?—They are constructing reservoirs. In the valley in which the unfortunate Bradfield reservoir gave way, they are constructing two reservoirs, one immediately above and one higher up, and in the adjoining valley called the Agden valley they are constructing a very large one. The new reservoirs which they obtained the Act of Parliament for last year are eight or nine in number, and their embankments vary from 66 to 94 feet in height.

6557. Are you carrying out those works?—No, Mr. Hawkesley is the engineer to them. I originally chalked out the first great extension which they made, but the works were carried out by Mr. Leather and Mr. Gunson, the resident engineer. I am to some extent responsible for the general arrangements of the scheme, but not for the sites of the reservoirs. When the embankment burst many gentlemen were called in, amongst others Mr. Harrison, to report upon the cause of the destruction of that embankment, and after the Act of Parliament was passed Mr. Hawkesley was appointed engineer to the company, and to the new embankments of last session. There are seven new reservoirs, and the heights of the embankments vary from 66 feet to rather more than 94 feet, 66, 74¾, 80½, 82, 90½, 94 feet 2 inches, and 94 feet 4 inches.

6558. Having as you have stated this very large gathering ground, and an amount of water far in excess of what in your opinion they can require, would they be able to supply with water the towns that are below them on the same line of country?—They would, and I have no doubt that that will be the ultimate result, because they cannot use all the water that they have acquired, and they will supply the distant towns exactly in the same way as Manchester is now supplying places far distant from the hills.

6559. Will you put in some population returns about which you were asked yesterday?—I was asked yesterday for some particulars respecting the population in Lancashire. I find that the total population of the county of Lancaster in 1861 was 2,429,440, and that of the towns of which I gave a list yesterday amounts to about a million and a half. I find that in the larger places, towns exceeding 3,000 inhabitants, up to large places like Liverpool and Manchester, nearly all of which are supplied with water, there are 1,648,000 persons in round numbers, and the populous villages, of which I have a list, that is to say parishes and places varying from about 2,000 to 16,000, put together come up to a population of 187,000 and that makes a total of 1,834,000 out of 2,429,440, the remainder being rural population in scattered places. And in this table I have marked with a cross all those places, which, as I happen to know of my own knowledge, are supplied with water by means of waterworks either in the hands of companies or of the local authorities. There are some places which I have every reason to believe are supplied, but I cannot positively say so, which I have marked with a point representing a doubt, and amongst those there are other places which are supplied in whole or in part from wells in the new red sandstone, which I have marked with a circle; so that this table will show at a glance the condition, so far as I am able to state it to the Commission, of the water supply of the principal places in the county of Lancaster. You will find that there are very few places in the table to which I have not attached a mark signifying my own knowledge of their means of supply. Other places there may be, but I have not the means of stating whether there are or are not, positively. I beg leave to hand in the following table:—

COUNTY OF LANCASTER. Population taken from the Census Tables of 1861.

The places marked in the accompanying table with a * are now supplied with water by means of waterworks in the hands of companies or local authorities.

Those marked ? are believed to be so.

Those marked thus o are either wholly or partially supplied from wells in the new red sandstone.

6560. Will you now proceed with your evidence upon the subject of the reservoirs?—I stated in answer to a question from Mr. Harrison in my former examination, that the surveys were made from actual observation, that is to say, the reservoirs and embankments were computed from actual observation, and they were so by the aneroid barometer principally. A doubt was expressed as to whether the reservoirs were so large as I had stated them, and, therefore, to determine that point, and entirely set it at rest, I have had every reservoir accurately surveyed and sections of the embankments taken, and actual surveys made since then. I am rather glad to have an opportunity of correcting my evidence upon that point, because not only in the quantity of earthwork in the embankments, but in the capacity of the reservoirs I find that I was very much within the truth as to the capacity of the reservoirs, and over the truth as to the cubical contents of the embankments. I will hand in a table showing the total capacity of the reservoirs and other particulars upon an accurate re-survey. The mean of available rainfall, as I showed yesterday, of three consecutive dry years for the whole district was 50 inches; and assuming 120 days of drought, the reservoirs, and dry weather volume of the streams would afford a supply of 379,000,000 gallons daily to streams and the city, and that if measured by that number of days and the springs taken into account represents 46·6 inches obtained from the ground. That is exclusive of the district which is marked upon the map behind you with green streaks, which is a large portion of the river Severn proper, and which Mr. Pole recommended should be included in the scheme, which I had previously rejected on account of there being lead workings at the time I examined the ground in the first instance. Those lead workings are discontinued, and that district therefore might be taken into account. But if, excluding that area, and confining ourselves entirely to the area which I had the honour of laying before the Commission on the former occasion, we supply this quantity of water, which is equivalent to 250,000,000 gallons a day to the metropolis, it would be equal to a collection of 46⅔ inches from the ground.

6561. (*Sir J. Thwaites.*) When you make use of the term "collected," do I rightly understand you to mean that 46 inches is the net result of that which is available for supply?—It may or may not be. If we were to discharge from those reservoirs 220,000,000 gallons a day, and we assume that the streams throughout on the average of the whole of those 120 days gave 30,000,000 gallons a day, that would be a total discharge of 250,000,000 gallons to the metropolis, besides the quantity of water which would be discharged to the river, which would be about 90,000,000 gallons a day more. If all that water was discharged, it would be equal to a collection of water over the whole of that surface of 46⅔ inches. If we measured the discharge by 140 days, so as to make the reservoirs last out 140 days instead of 120 days, and assumed the average volume of the streams during that time to be 25,000,000 gallons, that would be equivalent to a collection and discharge of 40½ inches of water. I showed yesterday that you might reasonably expect 50 inches as the available supply on the average of two or three consecutive dry years. Those are all the particulars which I have to give with respect to the reservoirs, and I may state generally, before I hand them in, that the gross capacity of the reservoirs, as I stated them on the former occasion, was in round numbers 5,709,000,000 cubic feet; the re-survey brings up the quantity to 6,709,000,000 cubic feet. Therefore I stated them 20 per cent. less than the proper quantity. You will find the sections of all the reservoirs, the Trefeglws reservoir and the rest, one after the other. The table contains every calculation with regard to them. (*The witness delivered in the following table.*)

J. F. Bateman, Esq.

5 March 1868.

PARTICULARS OF RESERVOIRS proposed to be constructed in the Welsh Scheme.

District.	Drainage area.	Height of embankment.	Area of surface of reservoirs.	Total capacity.	
				Cubic feet.	Cubic feet per acre of drainage area.
	Acres.	Feet.	Acres.		
Vyrnwy and Banw District:

	Reservoirs as laid out will supply			
	For 120 days.		For 140 days.	
	Compensation to streams at 9 inches of rain.	To the city.	Compensation to streams at 9 inches of rain.	To the city.
	Gallons.	Gallons.	Gallons.	Gallons.
Vyrnwy and Banw District.	37,118,487	144,817,383	37,118,487	118,826,544
Severn proper District.	35,910,144	131,567,644	35,910,144	107,642,244
Totals	73,028,631	276,385,027	73,028,631	226,468,788
Streams during these periods will yield about ½ a cubic foot per second from every 1,000 acres—say from 130,572 acres	—	30,000,000	—	25,000,000
Totals	73,028,631	306,385,027	73,028,631	256,468,788

Mean available rainfall of three consecutive dry years for the whole district	50 inches.
Assuming 120 days drought, reservoirs and dry weather flow of streams will afford a supply of 379,413,658 gallons daily to streams and city, being equal to an available annual rainfall from the whole district of	46·621 ins.
Assuming 140 days drought, reservoirs and dry weather flow of streams will afford a supply of 329,497,414 gallons daily to the streams and city, being equal to an available annual rainfall from the whole district of	40·595 ins.

In the plans and sections which I will also hand in the reservoirs themselves look very small, but they are from the same scale as the Ordnance Survey. The sections are upon a larger scale. (*The witness delivered in the same. Vide Appendices.*)

6562. (*Chairman.*) Have you anything more which

J. F. Bateman, Esq.

5 March 1868.

you wish to state with regard to the reservoirs, or have you done with that part of the subject?—I do not think that I have anything else to state, except that the embankments vary from 70 to 80 feet, the highest. There are three reservoirs at 80 feet, one at 70, and two at 76, and I may state that in the Dulas valley, which is the one through which the railway goes, I have not estimated actually for the reservoirs which have been laid out, but I have taken an estimate of the other reservoirs at the proper quantity for that valley on the scale of the other reservoirs, assuming that I can find other sites for reservoirs as good elsewhere, and not the lowest price but the highest price.

6563. (*Sir J. Thwaites.*) What is the internal slope of the 80 feet reservoir?—Three to one. The estimate includes every expense. The situations are remarkably good; it is impossible to find better ground anywhere in the world. The materials of which they will be constructed are also equally good, and the estimate includes a considerable amount of what is called beaching on the slopes where the banks are clay, for the purpose of preventing the discolouration of the water. I do not think I can go further into that matter than I have done.

6564. (*Chairman.*) Have you, since you gave evidence before, looked into and revised the estimate which you then gave?—Yes, I have gone carefully over everything, and the estimate, including the arrangements for connecting with the existing water companies, I have prepared in great detail. I thought it better to give it in detail for the purpose of examination. I have prepared it for a supply of 230,000,000 gallons. The total supply which the works are laid out with reference to at the various stages is 130,000,000 gallons, 170,000,000 gallons, 200,000,000 gallons, and 230,000,000 gallons, and I have also estimated what the additional cost would be if it were laid out with a view to ultimately obtaining 300,000,000 gallons a day from this district. The whole difference between the estimates which I laid before you on a previous occasion and the present estimates is 140,000*l.* more in the present one. I had not then gone anything nearly so carefully into the mode of connecting with the existing companies as I have since done, and when the whole quantity is brought it will be about 1,000,000*l.* more than it was previously estimated, owing to the extra cost which appears to attend the connection with the existing companies. Here are the particulars of the estimate in gross, and the particulars of the watercourses.

6565. (*Sir J. Thwaites.*) What are the particulars in gross?—The gross estimate, exclusive of interest on money, current expenses, superintendence, and engineering, for obtaining 230,000,000 gallons, and exclusive of the cost of connecting with the existing companies, is 9,317,205*l.* I have added 10,000,000 gallons to the former estimate, as I find that everything will carry 10,000,000 gallons more. I measured the capacities of the works by the size of the reservoirs. The reservoirs were larger than I had anticipated, and I have added 10,000,000 gallons in consequence, and they now will give 230,000,000 gallons against 220,000,000 gallons as before estimated. I have measured the capacities of the district, not by the water to be collected, but by the size of the reservoirs, for 230,000,000 gallons, and distributing it to the existing centres of supply in London, and including every expense attending the connexion with the works of the existing companies in the re-arrangement of pipes and whatever will be required, it comes to 10,317,205*l.*

6566. Your previous estimate for the smaller quantity was 10,850,000*l.*, was it not?—Yes, but there has to be added a sum for interest of money during the construction of the works, and for engineering and superintendence, and then if you add about the same amount that I allowed before, which was 1,140,000*l.* or something of that sort, or rather more, perhaps, say about 1,500,000*l.*, which would be something like it, that would make it 11,800,000*l.*, including all the current expenses of superintendence, engineering, legal expenses, Acts of Parliament, and other things.

6567. (*Col. Harness.*) Does that include the supply reservoir near London?—Yes, that includes the supply reservoir near London, and all the pipes from thence to connect with the existing companies. Then if you take it at 130,000,000 gallons only, which is the first instalment, the total cost of that in outlay will be in round numbers 7,600,000*l.* That includes reservoirs near Edgware or near Stanmore. They are about equally distant from each place, and it includes connexions with the existing works of distribution. From that I deduct the value of the property which may be disposed of supposing the new water were introduced. There are various chief rents which in themselves are of a very considerable value, especially those belonging to the New River Company, and the land and engines, pipes, and other things, and a low estimate upon these I think is 1,000,000*l.* Therefore I deduct 1,000,000*l.* for those things which would be set at liberty, so that 6,602,000*l.*, exclusive of interest of money and so on, is the net cost of obtaining 130,000,000 gallons, and of connecting the supply with the existing distribution arrangements in the metropolis. I will show why I take 130,000,000 gallons. That appears to be something like the quantity which will be required by the time the works can be executed, and by the time the water would be introduced. Then I go on with an estimate for 40,000,000 gallons more, making 170,000,000 gallons altogether. That I apprehend, from the evidence which has been given, is the quantity which the witnesses calculate upon obtaining from the Thames and the Lea together, without the construction of reservoirs upon the Thames or upon the Lea. The total cost of obtaining that quantity will be in round numbers 8,500,000*l.*, that is also exclusive of interest on money, superintendence, and other things. And for the third instalment of an extra 30,000,000, which brings it up to 200,000,000 gallons, which is a good convenient round figure, the estimate is about 8,750,000*l.* And for the fourth instalment, which brings it up to 230,000,000 gallons, which is about the scale of the works as laid out, the amount is brought up to 9,300,000*l.* I have omitted in this estimate the interest on the money and other expenses of that nature, because I have to compare the amount which I have given with the cost of obtaining the same quantities of water from the Thames and the Lea, in order that you may see exactly, as nearly as I can estimate it, the comparative cost of obtaining the water from both sources; and as the expense is in some cases rather more, and in some cases rather less, the interest of money you will be able to determine without reference to the actual cost of the works to be constructed. This view supposes that the works in either case had to be completed before water was supplied. I will now hand in a summary of the estimated outlay for obtaining and distributing the supply from Wales, upon which I have just given evidence.

WELSH SCHEME.—SUMMARY of ESTIMATED OUTLAY for obtaining the supply from Wales and distributing same to existing centres of supply:—

1st instalment of 130,000,000 gallons daily:		
Reservoirs and works for collecting and storing water in the Vyrnwy and Banw district, including land and contingencies - - -	£489,882	
Branch aqueduct from river Banw to Marten Mere, including land and contingencies - - -	599,137	
		£1,089,019
Main aqueduct from Marten Mere to service reservoirs near Edgware. Syphon pipes capable of discharging 130,000,000 gallons daily		5,453,359
Amount carried forward -		£6,542,378

Amount brought forward - - - -		£6,542,378
Service reservoirs near Edgware, and distribution of water to the various districts. - -		1,059,810
Total cost of obtaining first instalment of 130,000,000 gallons daily - - -		7,602,188
Deduct value of property which may be disposed of as soon as supply by gravitation is introduced - - - - - - -		1,000,000
		£6,602,188
2nd instalment of 40,000,000 gallons additional:		
Reservoirs and works for collecting and storing water in the river Severn proper district, including land and contingencies, £570,291		
Branch aqueduct to Marten Mere, including land and contingencies 492,117		
	1,062,408	
Additional syphons on main aqueduct from Marten Mere to Edgware - - - - - -	266,650	
Additional service reservoir near Edgware, and piping and other works for distribution of water to the various districts - -	557,551	
		1,886,609
Total cost for obtaining a supply of 170,000,000 gallons daily - - -		£8,488,797
3rd instalment of 30,000,000 gallons additional		
Additional syphons on main aqueduct from Marten Mere to Edgware - - - - - -	£133,324	
Additional mains and works for distribution of water - -	117,535	
		250,859
Total cost of obtaining a supply of 200,000,000 gallons daily - - -		£8,739,656
4th instalment of 30,000,000 gallons additional.		
Additional syphons on main aqueduct from Marten Mere to Edgware - - - - - -	£133,324	
Additional service reservoir near Edgware, and for distribution of water - - - - - -	444,225	
		577,549
Total cost of obtaining a supply of 230,000,000 gallons daily - - -		£9,317,205

These estimates are exclusive of interest of money and expenses during construction.

I will also hand in a statement of the particulars, together with estimates for the four instalments upon which I have calculated, and also a summary of the whole (*see Appendix M* (1)).

6568. (*Sir J. Thwaites.*) Is any other item excluded besides that of interest?—Nothing else is excluded but interest and current expenses. If you will allow me I will add to each of those items, as nearly as I can estimate it, the interest of money and the expenditure which will be required in superintendence and so on during construction. I will now lay before the Commission a map showing a portion of the line of aqueduct from Wales to London (*delivering same in*). This map shows the line of tunnel terminating at the service reservoirs near Stanmore, about a mile north of Edgware, and the tunnel terminates at a level of about 270 feet above ordnance datum. I am astonished that anything like sites for such reservoirs can be found so near the city of London. There are more than 500 acres in the two reservoirs which are colored red. They do not interfere with a road nor do they destroy a house, nor is there a house which overlooks them except two small villas, and you may make almost as many reservoirs as you like under similar circumstances underneath the hills there. The two which are marked red on the map I have specially surveyed, and I can give their actual contents and cost. The third, marked in red outline, has not been accurately surveyed. The new Midland Railway now runs right up the valley and that adds very much to the cost, otherwise those two reservoirs would have been joined by a short embankment. The embankment of the Midland Railway might have been used for the reservoir, but it happens to be some 16 feet too low, and therefore we are obliged to make the embankment alongside the railway and to terminate at a higher point. The greatest height of embankment is about 50 feet. (*The witness described the position of the reservoirs, &c. upon the map, see Appendix A N* (1)). As to the capacity of the reservoirs, you will observe that there is a section of the one embankment, and there is a section of the other embankment, and one cross section of each reservoir (*see Appendix A N* (2)). The reservoirs themselves will be from 35 to 40 feet deep.

J. F. Bateman, Esq.

5 March 1868.

6569. What is the height above high water at the mean point of your discharge?—It is about 270 feet above ordnance datum, and 257½ above Trinity high-water mark. This embankment at its deepest part, which is just in the valley, is 66 feet, and the height of the other is 68 feet at the lowest part. It runs parallel with the Midland about 30 feet, and I think it is 15 or 16 feet above the Midland Railway at its lowest point. The whole of this work would be in London clay, and there is not an arable field, there are a large number of green pasture fields rather swampy. Above the London clay we get abundance of gravel for beaching the whole surface, so as to prevent any disturbance of the side by the agitation of the water by the wind. We excavate nothing except what is necessary for the formation of the bank, and that will give us, by proper arrangement, a depth, except in the slopes, of 20 feet at the shallowest place; here is another sheet (*producing the same*), and you will see that there is not a road nor a house upon the site.

6570. (*Mr. Harrison.*) With regard to these reservoirs, and with regard to those in Wales, you think you have obtained sufficient information from actual survey to enable you to make as correct an estimate as you would make if you were going to Parliament for an Act?—Just the same. Those two reservoirs contain 21 days' supply upon 130,000,000 gallons a day, and you may make as many more almost as you like in the same way; by tunnelling through another part of the ridge and coming to the head of an adjacent valley, you may repeat the reservoirs there. That answers very much the question which was asked before as to the danger of depending upon one source only for the supply of London. You may construct reservoirs there which will contain I should think something like six weeks or two months supply, and you may defend them if you choose by fortifications on the top of the hill; they would not be half so liable to disturbance as the pumping stations at Hampton or Thames Ditton, and you have from each four or five different pipes and means of communication which could hardly be discovered even by a hostile army, and you might get a supply of water which would last out a siege of two months, or by eking it out, of three or four months, independently of any external supply whatever. Those reservoirs are nearer to London and less liable to injury and are more defensible than the existing means of obtaining a supply. The capacity of the western reservoir is 1,230,000,000 gallons, and the capacity of the eastern reservoir is 1,549,000,000 gallons, in round numbers. In consequence of the Midland Railway the amount of earthwork has been very much increased. The total amount of earthwork in the two embankments is now 1,687,000 cubic yards, all of which will be excavated out of the reservoir and below high-water mark. That amount has been added to by the Midland Railway going up so unfortunately there, are perhaps that will increase it 300,000 or 400,000 cubic yards.

This map also shows the lines of communication with the existing waterworks companies. The upper red line starts from the eastern reservoir and runs in a south-easterly direction to the point at which it bifurcates into two branches. That aqueduct is exactly the same size as the Loch Katrine aqueduct and is laid out for the conveyance of about 60,000,000 gallons of water per day, with a fall of 14 inches in a mile. It is a covered aqueduct the whole way exactly on

J. F. Bateman, Esq.

5 March 1868.

the scale of the Loch Katrine aqueduct, and it brings all that water to a place called Crouch End, immediately above the north and east of London, at an elevation of 240 feet, so that you have the water brought immediately above London at an elevation of 240 feet. From there commence the arrangements for distributing the water to the east end of London. Then you have another pipe taken from either or both reservoirs, which will take the water to the Campden Hill reservoir of the Grand Junction and West Middlesex Water Companies, another pipe which will take it on to the Putney Heath reservoir of the Chelsea Waterworks, another pipe which will take it on to the Streatham Hill reservoir of the Lambeth Waterworks, and another pipe which will take it on to Blackheath, to the Kent Water district.

But before going into all these details, I must endeavour to explain to you the manner in which the town is now supplied. There are some plans (*producing the same*) which were prepared by Mr. Ranger in a report made by him to the Hon. William Cowper some years ago, showing the manner in which the town was divided into districts and the sources of supply.

There are three pumping stations at Hampton on the river Thames, the Grand Junction, the West Middlesex, and the Southwark and Vauxhall. The Grand Junction and the West Middlesex Companies by two partly different routes convey the water to Campden Hill, where they have service reservoirs. There the Grand Junction Company has erected a stand pipe for the purpose of supplying the higher districts, while the lower districts are supplied from the level of the Campden Hill reservoir; one reservoir is 124 feet and the other is 132 feet above the level of high water. I do not remember at this moment which belongs to the Grand Junction and which to the West Middlesex Company; the lower level reservoir I think belongs to the Grand Junction Company, and the higher level reservoir to the West Middlesex Company. The West Middlesex Company supply the lower portions of their district from that reservoir, and they pump the water for the higher districts to a reservoir 190 feet above the ordnance datum at Barrow Hill, and they have recently erected a reservoir at a still higher level. The Southwark and Vauxhall Company take their water from the same spot, and take it by a different route to Battersea on the south of the river Thames. They have no reservoirs at all, they pump the water with the aid of stand pipes for the purpose of reducing the friction, and they deliver the water to their district by pumping it up the stand pipe, and so get a pressure which supplies the district. Part of that is delivered at 180 and a small portion of it, for a very high point, at 350. I think that is the pressure upon their pumps. The Chelsea and the Lambeth Companies, which are the two remaining companies which draw their water from the Thames, take their water from Thames Ditton. The Chelsea Company by a much shorter route than any of the other companies take it to a reservoir at Putney Heath at 172 feet above the level of ordnance datum, and from there by an aqueduct across the river at Putney they supply the whole of their district. The Lambeth Company pump into two reservoirs at different heights. The one which I shall specially allude to is at Streatham, which is 197 feet high, which is high enough for the supply of nearly the whole of their districts; but there are high points at Norwood, the Crystal Palace, and places of that sort, which require a higher elevation still, and they pump into another reservoir for that purpose.

The Kent Company pump their water into reservoirs near Blackheath; there is one reservoir near Shooter's Hill, and one reservoir in Greenwich Park. I am not quite sure of their arrangements, but they supply I believe from those reservoirs.

Then there come the East London and the New River companies. The East London Company take their water from the river Lea now at two points which are almost the lowest, and which are in the very heart of the district which they have to supply, and therefore they have not the difficulty and expense of overcoming the friction. Instead of having to convey the water before they get to their field of distribution 14 or 15 or 16 miles, as all companies, except the Chelsea Company, have to do who draw water from the Thames, they are at once in the heart of the district, and save at least 150 feet of pumping head in consequence of that advantage. The New River Company also come by gravitation to a point of distribution in the heart of their district, and they bring their water by a canal at something like 100 feet above ordnance datum, so that they have to lift 100 feet less than the other companies, and they have no amount of friction to overcome. The result is that those two companies are pumping at half the cost of the other companies, and they have a great advantage in that respect. They also differ in their mode of distribution, or at all events in the mode in which the distribution is effected. The New River Company pump their water by rotatory engines, and so do the Chelsea and Lambeth companies, into reservoirs, and from those reservoirs they take their supply. The East London Company raise their water by a large number of Cornish pumping engines, (as the Southwark and Vauxhall, and the Grand Junction companies, and the West Middlesex, I believe do to a great extent,) and they supply without a reservoir by keeping up the pressure upon the pipes according to their demand, increasing or knocking off the horse power at work according to the varying demands of the day. It so happens that the elevation of the Stanmore reservoirs gives the means of communicating with every one of the reservoirs (except the very high point reservoirs), which are used by all the existing companies, and giving full pressure in every district, always excluding the very high points, which refer to a very small population, perhaps 1/70th of the whole. The highest reservoir of the New River Company is the Maiden Lane reservoir, which is at an elevation of 231 feet 5 inches. I mentioned that the termination of the aqueduct which would be made in continuation of the main aqueduct from Stanmore for the express service of that district will be at 240 feet, therefore I have a difference of 8 or 9 feet for a mile and a half, and I can easily supply that.

But before going to that point, I must state that instead of having as there are now eight different companies supplying eight different districts, it would be convenient, supposing a fresh supply of water were introduced, and the companies purchased or absorbed in any new arrangement, that the whole metropolis should be divided into four or five districts, one being a compound district consisting of one pipe for two districts. The East London and New River should go together, and I have endeavoured to show that by the red marginal line on the plan, which shows the manner in which all those districts which are now distinguished upon the original map by the red colour and the brown colour should go together. Then the Grand Junction, the West Middlesex, and the Chelsea Companies, which you see interlace very much with each other, should also be formed into one district. The Barrow Hill reservoir of the West Middlesex Company should be used for the high portions of the Grand Junction and the West Middlesex districts, and the two reservoirs which supply the lower districts of those two companies should be used as they have hitherto been. The Chelsea Company might be treated in two ways. I propose to take a pipe in continuation of the pipe from Stanmore, from Campden Hill down to the 30-inch main which is the main pipe of the Chelsea waterworks, and join it near the point at which it commences its distribution; all the water would be put into that pipe, and no alteration of pipes would be required. On the southern side of the Thames I propose that the Lambeth and Southwark and Vauxhall districts should be combined; at present you see they not only interlace, but a portion of the district is supplied by both companies distinguished by a sort of neutral tint, the Lambeth district being distinguished by the blue, and the Southwark and Vauxhall by the red, and a portion is coloured

with both colours, showing that in that district both companies have the supply of the water. Then the Kent district, which goes quite to the east on the south side of London, might be a district by itself. Then I have taken the quantity of water which is now supplied, and the probable rate of increase, which I think is the next point in the determination of this question.

6572. (*Mr. Harrison.*) Your view is to deliver the water into the existing reservoirs of the companies, and that there would be no change after that in the present arrangement of their works?—There would be no necessity for changing a pipe as far as the arrangement of the works was concerned. I should in all cases take the pressure at the present fountain heads of distribution.

6573. And you leave the question of constant high-pressure service untouched?—Yes.

6574. In fact any expenditure under that head would be the same in one case as the other, to convert the present system into a high-pressure system?—Yes, that would be a very small expenditure.

6575. (*Chairman.*) You have given us now your views as to the best mode of districting London for the supply of water, what effect do you contemplate that would have upon the existing companies; what is in your mind when you district London in this way?—I propose that all the companies should be abolished, as companies, and that they should be absorbed by a general water commission or a corporation, as it is in Manchester and Glasgow and Liverpool, for the supply of water, and that they should be allowed to levy a compulsory rate upon every house and upon all property. But you will see that by this arrangement every company would have its water exactly as it has had it, and that each company might still continue to distribute as it has done. I do not think that the companies ought to exist.

6576. That is another point; but your own plan would be to annihilate them all?—To absorb them all, guaranteeing to them upon the security of the public rates their present dividends, or whatever might be declared to be upon proper arrangement the fair annual value of their property, or to buy them up.

6577. But supposing it were thought advisable that the existing interests should be left untouched, would your scheme be applicable to such a state of things?—Perfectly so.

6578. Will you be kind enough now to explain to the Commission how the existing interests of all the water companies and their dividends and their status might be retained and your scheme passed?—By the line of aqueduct which will end at Crouch End, below Highgate, water could be conducted to the New River Company's reservoir at Maiden Lane, which is their highest reservoir. In the arrangement which I propose, I propose that all their very low service reservoirs which do not give a proper high pressure should be abandoned. At present the New River Company force their water up through pipes to Maiden Lane. I would put the water into the Maiden Lane reservoir at the top, and the water would go down the pipe instead of being forced up; therefore they would have their water at the highest point to do as they chose with. I further propose to continue the pipe from Crouch End to the reservoir at Hornsey, for the construction of which the East London Company obtained power last session, which is 140 feet above datum. There they may do what they like with it; they may take it down to Lea Bridge if they please. I have estimated the cost of taking it down to Lea Bridge and putting it into their very starting point. The only difference would be that they would get their pressure by gravitation instead of by the exertion of horse power to give it artificially.

6579. You take Crouch End as the end of the aqueduct, but what is the state of matters as it exists at the present moment? how is the water put into that reservoir made available for the purposes of the New River Company?—There would be no reservoir at Crouch End except a mere basin, the reservoir would be at Stanmore. Maiden Lane reservoir which belongs to the New River Company is 231 feet above the ordnance datum, and they pump the water there by steam power into the reservoir.

6580. Where do they draw it from?—From the river Lea. The New River water starts at Hertford from the river Lea, and by the New River they bring it into the heart of their district at an elevation of 100 feet above ordnance datum.

6581. (*Sir J. Thwaites.*) The point is not the mechanical question as to whether you can put the water into the various pipes and mains of the existing companies, but financially how would it be possible for you to carry out your scheme except on the condition that the several water companies were absorbed. You have now brought yourself into the condition of a wholesale supplier, and you have certain existing companies which have statutory powers to supply, and large sources of supply, and unless you absorb those existing companies it is quite clear that they might refuse to take your water, although of much superior quality to that which they supply, and Parliament would never drive them to it?—I have a very strong opinion upon that point, that the companies ought to be abolished by proper arrangements. They deserve well of the inhabitants of London, they have supplied them with water when they would not supply themselves, and therefore they deserve well of the public, and they ought to be properly and handsomely paid for their position in the same way as the old Glasgow Company and the Gorbals Company were paid in Glasgow, and two or three old companies in Liverpool, and the old company in Manchester, which were all paid and handsomely paid by the corporations.

6582. Does not your scheme proceed upon the assumption that the whole of them must be absorbed?—It does. It is not necessary that they should be absorbed, but I should be very sorry to be engineer to a scheme which did not absorb them.

6583. (*Mr. Harrison.*) If not absorbed, would it not be necessary that they should be compelled by Parliament to take your water and to distribute it?—Yes, everybody in London ought to have water, and everybody no doubt gets it more or less, and if they do not pay for it they steal it. That is a state of things which ought not to exist. You ought to place water within reach of everybody, and compel everybody to pay according to the property occupied, which may be considered to be according to their means. I would compel them to pay for so great an advantage. Then all property ought to pay because you reduce the chance of fire. I am able to show very important evidence upon that point. You improve the health of a town by an increased supply of water, and you increase the value of property, therefore all property of all kinds ought to pay a small rate, and for domestic supply specially a higher rate, and in that way you would not have occasion to levy from the inhabitants as large an amount per head as they pay now, to defray the whole cost of this undertaking. I have brought all this before the public in a purely disinterested way, for I am only anxious to give all the information which I possess upon the subject, and I should be sorry to advocate the continuance of the companies. I am so convinced of the great advantage which would result from this water supply being in the hands of a great corporation for the benefit of the whole metropolis, that I would not advocate a scheme which did not include that idea.

The present quantity of water, that is, the average quantity of water which was supplied in 1866 (and I take 1866 for a particular reason), was 95,000,000 gallons. London, as you are aware, has doubled itself in 40 years twice over, and if you are to judge of the future from the past, and there seems to be no present reason for supposing that that proportion will diminish, it will go on increasing at the same rate, and therefore the present population, which is rather more than 3,000,000, will in 20 years be 4,500,000. The increase of population from 1851 to 1861 according

J. F. Bateman, Esq.

5 March 1868.

to the census returns was at the rate of 1·73 per cent. per annum, and the increase in the water supplied from 1856 to 1866 which you see overlaps and includes a portion of the other decennial period, according to the returns of the companies, was rather more than 2½ per cent. per annum, although the population had increased only at the rate of 1¾ per cent. per annum.

6584. (*Col. Harness.*) Had not the companies extended their areas of supply?—I think not, but that would not affect the calculation. They might have extended their area (I do not think they have), they had increased the water supply from 1856 to 1866. Their works of improvement and extension were constructed between 1852 and 1856, and from that time they would very likely have extended their area a little; but from 1856 to 1866 they had not extended their area. The population of the area included in their water supply increased at the rate of 1·73 per cent. and their actual supply increased at the rate of 2½ per cent. The increase of water supplied in 1867 over 1866 was 3·9 per cent., in that year it was 4 per cent. per annum in round numbers greater than it had been; and if the increase in the population between 1866 and 1867 had remained as it was according to the last census, it would have been 1¾ per cent., whereas the whole increase in the water consumption was 4 per cent. If then in 1867 the increase in the population remained the same as it had been in the decennial period ending in 1866 it would be 1·73 as against 4 of increase in the water supply.

6585. (*Sir J. Thwaites.*) You are of course aware that during the exceptional period to which you have referred, the abolition of cesspools, and the adoption of waterclosets to the extent of many thousands in the metropolis, has greatly increased the demand for water?—I daresay it may have done so.

6586. But that increase will not run an equal race with the population for the future, because all houses are adapted for the supply, or as a rule it is so?—No doubt, but we find that from the more luxurious habits, and greater habits of cleanliness, and the use of the bath to a very much greater extent than formerly in all places, the consumption of water is increasing regularly year by year more rapidly than the population. In 1856 the supply was at the rate of 28 gallons per head per day, in 1866 it was at the rate of 31 gallons per head per day, and in 1867 it was at the rate of 32 gallons per head per day. If you take 32 gallons per head per day as the consumption, and estimate the population in 1877, nine years from the present time, at 3,650,000 persons, which it would amount to at the rate of 1·73 per cent., you will want 117,000,000 gallons a day. If you take the increase at the rate of 2½ per cent., you will want 127,000,000 gallons a day at that time; and if you take it at 3 per cent., which with all deference I think ought to be what you should take it at, you will want in nine years from the present time 132,500,000 gallons a day. Judging from the experience of all the places that I know, I think that is about the right amount to take, and my own belief is that when you get water which can be supplied by gravitation, when you include everybody as you ought to do upon the principle which I have laid down, and compel them to pay for water, and therefore give them an inducement to take it and use more than they have done, when you have converted every privy into a watercloset, and when you have water of the softness of Welsh water, in which case you would sell as much again for trade purposes as you do now, that is an under-calculation instead of an over-calculation, and my belief is that before nine years are over you will want more than 130,000,000 gallons a day. However, I have assumed 130,000,000 gallons, because that happens to be the scale on which I devised these works when I first laid them before the Commission, and that seems to me to be the quantity which may be required about the time at which they could now be executed; therefore in the table which is now before his Grace I have allotted that quantity of water as nearly as I could according to the apparent increase in the different districts. 95,000,000 gallons being the quantity in 1866, 35,000,000 gallons more are required to make up the total quantity of 130,000,000 gallons. I have added in round numbers 25 per cent. to the New River Company, whose tenants are not increasing quite so much as the others; I have added 40 per cent. to the East London; 15 per cent. to the Chelsea, which is confined to a limited district, bounded in on both sides, and therefore not likely to extend so much as the outer districts; 50 per cent. to the West Middlesex, which is a large district; 50 per cent. to the Grand Junction, which is in the same position; 50 per cent. to the Southwark and Vauxhall, which is also in the same position; 25 per cent. to the Lambeth, which does not seem to be increasing so much as the others; and 50 per cent. to the Kent, which is a large district to the east, making up 35,000,000, or a total of 130,000,000 gallons.

TABLE A.

TABLE showing the probable Proportion of the first Instalment of 130,000,000 gallons per day required by each Company's District.

—	Present supply (1866).	Proportionate addition.	Estimated requirements in 1875 or 1876.
New River - -	23,000,000	5,600,000	28,600,000
East London -	19,300,000	7,300,000	26,600,000
Chelsea - -	8,000,000	1,150,000	9,150,000
West Middlesex -	8,250,000	4,350,000	12,600,000
Grand Junction -	8,700,000	4,600,000	13,300,000
Southwark and Vauxhall.	12,700,000	6,700,000	19,400,000
Lambeth - -	9,000,000	2,250,000	11,250,000
Kent - -	6,050,000	3,050,000	9,100,000
	95,000,000	35,000,000	130,000,000

I have already stated that it is proposed to divide the metropolis, according to my idea of what it ought to be, into four districts (or into five, taking the Kent district), and those four districts are so evidently convenient that I think you will agree with me that that should be done. Taking the Lambeth and the Southwark and Vauxhall district, I have divided that into a low-lying district and a high-lying district. Then the supply required, according to the figures which I have just now read, for the New River and the East London together, are 55,200,000 gallons in a day; that is the first district. In the second district, in which are included the Grand Junction, the West Middlesex, and the Chelsea, the supply required, according to the same figures, is 35,000,000 gallons a day. In the higher parts of the Lambeth and the Southwark and Vauxhall districts, which are most to the south, the supply required will be 10,000,000 gallons a day, and in the Kent district, which is a further district, and a good deal of it a high district, 9,000,000 gallons, making 19,000,000 gallons, and in the lower parts of the Lambeth and the Southwark and Vauxhall districts near the river, 20,650,000 gallons. The level of the top of the water of the proposed service reservoir at Stanmore, as I have stated, will be 270 feet above datum, or 257½ feet above Trinity high water. I will now take district No. 1, which is the East London and New River district; the water will be conveyed by the aqueduct which I have already mentioned to Crouch End, and from the end of the aqueduct it will be conveyed to the Maiden Lane reservoir, as I have explained, to the new Hornsey reservoir, as I have also explained, and to Lea Bridge. Then the aqueduct will be of the same size as the Loch Katrine aqueduct, and I have taken the price of that aqueduct at 7*l.* a yard, which is a little more than a much more difficult length of the Loch Katrine aqueduct, the Duntreath contract, on which there was a tunnel and deep cutting, and besides that it is all covered, and there are various

bridges, none of which would be required in this work; but in order that I might give you no doubtful estimate, I have taken the actual price of that and added a little to it, and I have put it at 7*l.* a yard, that comes to 184,864*l.* There are some particulars which I think I need hardly go into, as to the level of the aqueduct and of the various reservoirs. If you will refer to the tables which I have put in, you will find that the New River will require 28,600,000 gallons. A 4-foot pipe will deliver 29,395,000 gallons after adding 25 per cent. to the theoretical discharge, as deduced by formula. That 4-feet pipe, with a fall of 7 feet in a mile, which there exists, will deliver 29,000,000 gallons in round numbers, and 28,000,000 gallons in round numbers are required. I have here a piece of pipe (*producing the same*) 5 inches in diameter, which was laid down at Cheetwood, near Cheetham, in the Manchester waterworks, in the year 1851. It was broken by the excavators last month, and I had it sent up to me for the purpose of showing the Commission what the result of the coating of cast-iron pipes by Dr. Smith's process is. I introduced the process into Manchester for the first time, and I coated all the pipes myself, and that pipe has been down 17 years. Externally it is just as fresh as the day it was put down, and internally it is almost in its original condition after 17 years' wear.

6587. (*Mr. Harrison.*) Have you reason to believe that the rest of the pipes are in as good condition as that?—Yes; all the pipes which I coated myself or under my own superintendence are as good as this, and I have seen some which have been taken up that were even better than this. But the pipes which were coated in Glasgow were coated by an ironfounder, and I will never again in a great contract allow the ironfounder to coat pipes. I will do them all under my own superintendence because they are so much better done. The mode of coating is this:—The Manchester pipes after being cast by the ironfounder, as soon as they were dressed, the sand dressed from them, and they were clean, and while they were warm, were coated with oil or immersed in oil, and in that condition they were sent to the corporation. They might then lie for some time, and they would contract no rust—it is very important to prevent rust—and then they were coated by being first heated up to about 300 degrees of temperature in a stove, and taken out of that stove while they were hot and immersed in a cauldron of boiling coal-pitch (after the naphtha was distilled from it) and oil—and that also heated up to 300 degrees of temperature; they were allowed to remain in this for a few minutes and then were gradually drawn out and cooled, and the pipes become coated with a perfect black *glaze.* The result of the coating in the Glasgow case was that the quantity of water which was discharged whilst they were quite fresh, from passing over this surface, which is like glass, was more than 50 per cent. in excess of the calculated results according to the formulæ; and although they were badly coated and not done with the care with which I should have coated them (and no ironfounder does it as it ought to be done), and many of the pipes have become rusty, they are now, through a pipe which according to the formulæ ought to discharge 19,600,000 gallons a day, discharging about 23,500,000 gallons or 24,000,000 gallons day by day.

6588. (*Sir J. Thwaites.*) Is that increased discharge caused by the small amount of friction in the pipes?—I suppose it is so. I only state the actual fact. So that adopting the proper mode of coating and reasoning from experiments, and from the actual result in the case of the Glasgow pipes, we are justified in taking upon those pipes at least 25 per cent. in excess of the computation which the mere formulæ would give. The East London supply which will be taken from the end of the aqueduct at Crouch End by another line of pipes would discharge an equal quantity of water, or more in point of fact, into their new Hornsey reservoir and deliver the water at Lea Bridge with a remaining effective pressure of 190 feet in the pipes. I believe they only lift their water about 140 feet, and therefore they would have an advantage of 50 feet of additional pressure, together with the full supply of water which would be required. I need not go through the details of the estimate, but you will find in the tables before you that that comes to 70,270*l.* The existing service reservoirs of the New River Company will be sufficient for their district. For the East London district it will be necessary to add to their new Hornsey reservoir, or to construct a new one of the capacity of some 14,000,000 gallons a day. I have only allowed in my scheme, as common to this as well as to any scheme, half a day's supply for the night supply, because those large pipes will be delivering their water constantly for 24 hours, and inasmuch as the demand at particular hours of the day is greater than the average demand during the period when the water is delivered, you are obliged to regulate that by having a reservoir into which the night water will be discharged for the purpose of keeping up the extra demand upon the pipes in the course of the day. Therefore I have allowed for service reservoirs where the existing reservoirs are not sufficient. From information which was laid before the committee on the East London Water bill of last year, and from other information of a public character, I have obtained the exact capacity of the various reservoirs, and have taken them into account whenever they were large enough.

J. F. Bateman, Esq.

5 March 1868.

Then No. 2 district, which is the Grand Junction and the West Middlesex and Chelsea combined, will receive this water by a 4-foot pipe from the service reservoir at Edgware, which will communicate with the Campden Hill reservoir of the West Middlesex and Grand Junction companies, and with the Barrow Hill reservoir of the West Middlesex Company. From the Campden Hill reservoir a 3-foot pipe will be taken to communicate with the Chelsea Company to join their 30-inch main, so that they will get the full additional quantity of water. The quantity required for the whole of this district according to the figures that I have given before is 35,500,000 gallons. The volume of water which a 4-foot pipe will discharge is 35,300,000 gallons, therefore that will be sufficient. Then the estimate for the 4-foot pipe and the 3-foot pipe together is 118,650*l.*

With regard to the No. 3 district, which comprises the higher parts of Lambeth and the Kent district, the quantity of water which they require is 19,100,000, the Kent district requiring 9,100,000, the Southwark and Vauxhall and the Lambeth together for this district 10,000,000. As to the difference of level I have taken all this into account, and I need not trouble the Commission with it. Those districts can be supplied with water from the Edgware reservoirs delivered into Streatham Hill reservoir, which only allows a fall of 4 feet per mile. The Streatham Hill reservoir is 197 feet high, and therefore it is within about 53 feet of the reservoir at Edgware, a considerable distance off; but allowing for all that, a 4-foot pipe brought from Edgware over the river into Lambeth will bring all the water which is required for the two districts. A 4-foot pipe is as nearly as may be double the area of a 3-foot pipe, and therefore it is equivalent to the service of two 3-foot pipes, and a 3-foot pipe to Streatham will deliver all the water which is required for that district; it will deliver 10,438,000 gallons a day, about 10,000,000 gallons being required; and a 3-foot pipe from the same point of bifurcation to Blackheath, for the supply of the Kent district, will deliver 13,000,000 gallons a day, 9,100,000 being all that is required, therefore those pipes are more than sufficient for the district. The estimate for that, including 50,000*l.* for the special bridge over the river Thames for the conveyance of the pipes, is 240,800*l.*

The No. 4 district, which is the low-lying district now supplied by the Southwark and Vauxhall and the Lambeth companies jointly, requires 20,650,000 gallons. One 4-foot pipe delivering the water into the reservoir at Putney, which is at present the Chelsea waterworks reservoir, and which I propose

J. F. Bateman, Esq.

5 March 1868.

to appropriate no longer to the supply of Chelsea, but to the supply of the Southwark and Vauxhall, will deliver 27,000,000 gallons to that reservoir, 20,650,000 gallons being what are required, and the cost is 162,750*l.* The summary of the whole estimate, adding all those sums together, and additional service reservoirs in the several districts, where the existing reservoirs are not sufficient for the purpose of regulating the supply in the day by impounding that which will come from the pipes in the night, is 1,059,810*l.*, including the service reservoirs at Edgware, the estimate for which is 237,438*l.*

I may perhaps observe that evidence has been given before the Commission that the cost of the reservoirs at Edgware would be from 800,000*l.* to 1,200,000*l.*, the mean of that is 1,000,000*l.*, but the actual cost upon a very full estimate indeed and double the real value of the land is less than one quarter of that amount. It was also stated that the cost of the re-arrangement of the pipes, and of conveying the water from the Edgware reservoir to the various different districts from whence it will have to be distributed, would be 2,000,000*l.*; the actual estimate, and it is a very proper estimate, as I think anybody will be able to see, is 750,000*l.*, and not a single pipe requires to be altered; the only change will be that pipes which will now become useless or too large for the various purposes of the supply may be taken up and applied to other purposes, but the water you see will be delivered into the nuclei of supply of the East London and New River companies just as they now supply it. It will also be delivered into the Lambeth district just in the same way, and it will be delivered into the Grand Junction and West Middlesex district exactly in the same way. Chelsea will be altered, for it will receive its supply direct from Edgware or from the Campden Hill reservoir, instead of taking it from the reservoir on Putney Heath, by a communication with the 30-inch main which conveys the water into Chelsea being made on the north side of the river, with a pipe from Campden Hill 36 inches in diameter. The Putney Heath reservoir will then be no longer appropriated to the supply of Chelsea, but it will be appropriated to the lower parts of Southwark, Vauxhall, and Lambeth, by a pipe taken from it and joining the Southwark and Vauxhall pipe at a point which it intersects on its way from Hampton to Battersea; a mere junction will do the whole thing. The Kent district will have a new reservoir near Blackheath in close proximity to the existing reservoir in Greenwich Park, with which it can be communicated, or a very slight additional bit of piping will put it directly in communication with the pipes which perform the service of that district. The change which will follow will be that the pipes from Thames Ditton into the district, which are nearly 20 miles altogether, will be rendered unnecessary. They are of various sizes, and the larger pipes which will be too large for their purpose may be taken up and smaller ones put down, or they may be used in some other way. Various pipes from Hampton also will be rendered unnecessary to a great extent, for they will be too large for that district, and they may be either continued or taken up and smaller ones put down. So that everything will be accomplished without disturbing any existing arrangements, and the Kent district, which it was confidently asserted could not be supplied at all, will be supplied with almost more effect and less cost than any one of the other districts, except those which are in close proximity to the large reservoirs.

6589. (*Chairman.*) With regard to the constant service, do you propose to give the Commission any evidence with reference to the constant service for the supply of London?—I had not intended to do so, but I shall be very happy to hand in a reprint of a paper upon the subject, which I read before the National Association for the Promotion of Social Science, and which I think will exhaust the subject pretty nearly (*handing in the same. Vide Appendix I.*). I may also mention that a great deal of evidence upon this very question was given for the East London Waterworks bill last session before a committee of which Mr. Ayrton was chairman, to which I may have occasionally to refer. I may state that my own opinion is that a constant water supply under high pressure in the existing state of the plumbing in London would be almost impossible, and that it is necessary that very stringent powers be given to the companies or to a corporation, if it had the administration of the water, to compel all the parties to put their water fittings into perfect order before the constant supply was given. Even the Welsh district would be almost insufficient to supply London under the constant system, as the fittings are now; but if proper care be taken that the fittings be all properly put in order, and a very strict supervision exercised, I find as a matter of experience that towns supplied under the constant system do not take more water than those which are supplied under the intermittent system. But one great and the principal source of waste is the watercloset, and also baths, which are now very largely introduced; in fact where the water is abundant and good there is sure to be a larger demand upon it, and a much greater quantity of water used than where it is insufficient and hard, and otherwise objectionable. It will therefore require on the part of anybody who may have the future administration of the water to be very stringent, and very careful in seeing that everything is properly adapted for the reception of the constant supply, otherwise London cannot have what I consider to be one of the greatest blessings, a constant supply.

6590. (*Sir J. Thwaites.*) With that efficient supervision you see no difficulty in applying the principle of constant supply?—I do not; I do not know how many towns I have supplied with water, but I have supplied I think something like 2,000,000 of people, and there are not 150,000 out of the whole of them who have not the constant supply.

6591. If with the constant supply you have the necessary inspection which you have referred to, and the mechanical arrangements suitable to constant supply and constant pressure, are you of opinion that it would rather economise than otherwise the quantity of water used?—I think it would, and if every adjustment is properly made it ought to economise it.

6592. Do you know the waterworks at Hull?—I am not acquainted with the waterworks at Hull, but I may state that in Manchester, where there are very few waterclosets in comparison to the population, and where baths are not common, the large bulk of the population consisting of the working classes, the consumption of water is now increasing. It was about 21 gallons per head per diem, it is now about 23 or 24 gallons per head. The consumption of water in Glasgow is 50 gallons per head per diem, where water fittings are as bad as they can be, as bad as they are in London (and that is about saying the worst thing for them), and the waste is very great indeed; I forewarned them against this, and for a time very active supervision reduced the waste after the introduction of the Loch Katrine water; but they consider that they have an inexhaustible supply and that it tends to sweeten the Clyde and flush out the sewers, and they allow the waste to go on, but all that might be corrected.

6593. Under the present system of supply in London, is it not the case that the companies shut off a certain area of distribution of water during certain hours in the day, and in case of a fire, unless the water is turned on to that district, there is no means of suppressing a fire in the metropolis?—That is so.

6594. But with the principle of the constant supply you would have water in every district, and although you may not be able to use it from a hydrant, still you would constantly have water which could be pumped upon a fire which might occur in this district?—Yes, the advantage of a constant supply in case of fire is very great indeed, it can hardly be overestimated, and I have the means of showing the Commission the result of an abundant supply of water

under high pressure in Manchester, from a report as late as the 8th of January 1868.

6595. What height can you throw water from your mains by means of hose?—When I laid out the supply of water in Manchester it was the first city which obtained the power of levying compulsory rates upon all property and upon all houses, and I thought it was only right that warehouse property, for instance, and other valuable property which did not take water for domestic purposes, should have the best possible protection and the greatest advantage that could be conferred upon them for their public rate, and I therefore laid out the pipes in the centre of Manchester, where the property was the most valuable, specially with a view to the extinction of fire and the protection of property, and there is no large block of buildings in Manchester which is not commanded within 100 yards by at least 20 fire-cocks. Fire engines have been discontinued, except as omnibuses to carry men and utensils. The pressure is such as will throw the water from the street over the highest building. The pipes are interlaced in such a way that the fire-cocks are not dependent for their supply upon one particular main, but the various mains are so interlaced that if one should be out of order or should be overdrawn other pipes would be able to deliver water. The result of that state of things is pretty much this—I have here before me a return of the amount of property destroyed and property saved on occasions when fires have occurred, from 1844 to 1867. The water was introduced into Manchester about 1851, but it hardly got into full use till about 1853. We had to change from the old intermittent system, as bad as anything could be, to the constant system, and we were very careful in taking it by districts, so that every district should be brought under the surveillance of proper officers, district by district, before we admitted it to the advantage of the constant supply, and in that way it was that we reduced the consumption so much. The per-centage of property destroyed from 1846 to 1850, before the introduction of the water, was 21·3 per cent. of the value of property attacked by fire. The amount saved out of such property was 78·6 per cent. From 1851 to 1855, Manchester, for half the time at least, not having advantage of high pressure, and for the latter two years of the time having it, and therefore it would be partly under the old system and partly under the new, the per-centage of property destroyed was 12·9 per cent., and of that saved 87 per cent. Then came the advantage of the constant supply and high pressure, with a full water supply, and from 1856 to 1860 the per-centage destroyed was only 7·7 per cent., being only one-third the amount which was destroyed before the introduction of the fresh water supply, and the amount of property saved was 92·2 per cent. From 1861 to 1865, the amount of property destroyed was 6·7 per cent., and the amount saved was 93·2 per cent. I do not think it is possible to have a stronger elucidation of the great advantage which arises in case of fire from a full water supply.

6596. Then you have reduced the loss from 21 per cent. to 6·7 per cent.?—Yes, taking the two lowest, it is from 21 to 7, and the increase in the amount of property saved is from 78·6 to 93·2. With the permission of the Commission I will hand in the following table (see p. 378):—

6597. (*Col. Harness.*) With regard to the loss by waste under constant supply, have you any experience of the effect of the delivery of water by meter in checking waste?—Yes; in the paper which I have handed in, there are a great many examples of that. The difficulty with the meter is the small quantity of water and the intermittent way in which it is drawn for house supplies. You could hardly supply a meter to individual houses, but you might put one to a district, and you might then see what the district was wasting, and in that particular district which was taking more than its normal supply you might introduce special investigations. That is one of the ways in which we manage to detect waste. The only difference between Manchester and London would be this, that having, for the purpose of showing how completely water could be supplied without disturbing the present arrangements, adopted the service reservoirs which now exist, in some cases they would not have quite the same amount of high pressure which we have in Manchester, but the higher service reservoirs which I propose to adopt are still high enough to give a very considerable pressure, and in most cases quite sufficient.

6598. (*Sir J. Thwaites.*) What is your head in Manchester?—I tried a number of experiments, and actually measured the height to which we could throw water, and I think we can generally throw water in almost every part of Manchester to a height of about 118 feet from the pipe, if I recollect rightly. By opening a fire-cock I have ascertained, by estimation and by a theodolite, that the height to which the water has been thrown has varied from 118 to 120 feet.

6599. With regard to the condition of the mechanical arrangements for the supply of water in the metropolis, what, in your judgment, would be the cost per house of putting them into such a state as to resist the pressure, and adapt them to the constant supply?—If the fittings are now, with the exception of the tap itself, such as are ordinarily put in, they would now be quite sufficient. I have changed the supply from intermittent to constant supply in a great number of towns, and I never heard anything like a complaint of the bursting of pipes by introducing the new system; in London plumbers are allowed to do whatever they choose, and not one of the companies exercises the slightest supervision over them; the probability is that they put in perhaps rather too strong than too weak fittings; but in all works with which I am connected I arrange the strength of the pipes according to the size, and according to the pressure, and the kind of tap to be used, and we require the plumbers to put them in. In very many cases corporations cannot do that, from the public outcry that is made; but in all private companies of which I can get the control, the companies do all their plumbing work themselves at a fair price, so as not to injure the plumber, and they make a considerable profit, and put in nothing but the best fittings.

6600. Do they use leaden pipes?—Yes, they use leaden pipes; wrought-iron pipes will not do; they corrode and burst. I tried them in my own house, and that was the result; but with leaden pipes and the best taps which can be employed, the whole cost of introducing water into a cottage house, for instance, is about 12*s.* to 15*s.*

6601. Is that the whole cost to make it fit for the constant supply?—Yes, that is the whole cost if you have to do it *de novo*, and surely it will not cost more to fit it for the constant supply than to do the whole thing afresh. Supposing there is any doubt about it, if you strip it all away, and put in a fresh thing, it will only cost 12*s.* to 15*s.* in a cottage house.

6602. Then are we to understand that the infirmity of the old system is rather due to the condition of the taps than to the pipes?—I believe that is the case everywhere. It may be that having been put in without supervision some of the pipes are too weak and will burst, but they will find themselves out very shortly; they may occasion a little annoyance in the first instance, but in the course of a week a weak pipe will tell for itself, and will burst, and you will have to put a stronger one in. Take any house in this neighbourhood, my own house in Great George Street, for instance, where the water is introduced into cisterns, I should make no alteration; I should use the pipes as they are. I would not incur the expense of 8*l.*, as has been mentioned, but I should have a plumber to see to the pipe which conveyed the water from the street, and if it was at a higher pressure, and by the arrangements which I now propose it would not be at a higher pressure, but if at a higher pressure I might change the ascending pipe from the street to the cistern, nothing more, and put a stop tap upon

ANNUAL COMPARATIVE TABLE of the NUMBER of FIRES that have been attended within the CITY OF MANCHESTER, showing the Origin of the Fires, Amount of Property at risk, Extent of Damage, and Value of Property not destroyed, giving the Per-centage of the Amount destroyed for the last 24 Years.

Period.	Number of Fires attended within the City.			Origin.												Time of Discovery.		Amount of Property at risk, insured or not.								Amount of Property destroyed.				Amount of Property not destroyed.

NOTE.—The particulars required in the blank spaces for the years prior to 1859 cannot be supplied, as the additional information returned since that time was not provided for in the original Fire Tables.

it; and then if I had any tap which was liable to run the water to waste I should change the tap and put a better one. That is all I should do, and that is all anyone would do with an old house; but if you were coming to a new house, in a great number of cases you would do without a cistern, because under the constant supply system a cistern is not necessary. Of course if the water should be shut off for a few hours, in order to attach any of the services, it is convenient to have a cistern, but it is not necessary; and the idea of spending 8*l.* or 10*l.* upon a house is preposterous. I am not speaking now as an engineer only, but I am speaking as a director of water companies, and I have had to do the whole thing, and know all about it. In answer to a question which has been put to me, with regard to how much the waste of water could be reduced, I may state a fact which occurred at Stockport. I happened to be the chairman of the Stockport Waterworks Company. There were some cottages which were supplied with waterclosets, and without any meters. A meter was put down by the gentleman who owned the property, and he paid by meter, and it was found that they took 80 gallons per head per diem. He was so astonished and so annoyed at having to pay such an amount for the water used, that he did away with the waterclosets, and he was supplied by meter for six months without waterclosets, and the consumption for other purposes than waterclosets was found to be 12 gallons per head per diem; so that waterclosets are the great consumers of water, unless they are of the best possible construction. Those were common syphon closets.

6603. (*Col. Harness.*) They must have been of a very vicious construction?—Yes, they are just the things which are introduced by local boards all over the country, and it requires proper supervision and proper authority to be vested in the parties who have to deliver the water in order to protect themselves against waste.

6604. What would you suppose to be the proper supply of water per head for waterclosets, would it be five gallons per day?—I should think that would be very abundant indeed; by the system which I now propose the water will be delivered to everyone. With regard to the existing system of supply to London, I will not take the Commission through the next amount, which is 40,000,000 gallons more, to bring it up to 170,000,000 gallons, but I will explain why I have taken 170,000,000 gallons, and I am going by-and-by to show you the cost of obtaining the extra 35,000,000 gallons over and above the existing supply, by pumping it from the Thames or getting it from the Lea, as compared with the cost of getting that same quantity of water, 170,000,000 gallons in gross, from Wales. In the evidence which had been laid before the Commission by some witnesses who ought to be very competent to give an opinion upon that point, they state that taking the Lea and the Thames together, 170,000,000 gallons may be withdrawn before the necessity for constructing storage reservoirs on the Thames arises, and therefore I have taken the cost of obtaining the water from the Thames and from the Lea under those circumstances with nothing more to do than to put down additional pumping engines and lay additional pipes, as compared with the cost of obtaining the same quantity in gross from Wales. I have gone all through and estimated in the same detail how much that would cost, and the detail is all upon the papers which I will lay before the Commission, including additional quantities up to 230,000,000 and 300,000,000 gallons per day.

I may state generally as I did before that I have had worked up in these various gradations the cost of obtaining water from the Thames and the Lea combined, and from Wales; and before I go through that I may state that I have examined the statements which have been made by the various witnesses who have spoken upon the capabilities of the Lea, and I find that it is cheaper to obtain water from the Thames than to incur the expense which those gentlemen give for obtaining it from the Lea. That I could show, and it is as well that I should do so, because I feel in this position, that inasmuch as I cannot undergo a hostile cross-examination, I am bound to make good every assertion I make, and although it may be tedious to the Commission, I am afraid I must ask you to bear with me whilst I show the ground of every assertion, that I may not be taken to have made any assertion without having ground for it. There were various estimates given, and perhaps I may as well state them. One was that an additional 10,000,000 gallons of water could be obtained from the Lea by an expenditure of from 300,000*l.* to 400,000*l.* on reservoirs. Then there was another, that 70,000,000 gallons could be obtained by an expenditure of 1,250,000*l.*, exclusive of compensation to mills and streams, the whole river having to be bought up if that amount of water had to be obtained. If you take 10,000,000 gallons additional, which is all they propose to take, there is not much difference between 10,000,000 gallons at 300,000*l.* and 70,000,000 gallons at 1,250,000*l.* with the additional compensation. In fact the 70,000,000 in gross would be rather the dearer arrangement of the two, and therefore I have taken the cheaper one, and allowing for the impounding reservoirs, for the engine power to raise 10,000,000 gallons, and for the annual cost of pumping, which I will show by-and-by, I find that the cost of obtaining that quantity of water, 10,000,000 gallons additional from the Lea, would be 597,000*l.* in round numbers, and that the cost of obtaining the same quantity of water from the river Thames would be only 504,000*l.* Therefore it is cheaper for the East London Company, as they thought last year, (and I advised them to do so,) and for the New River Company, to go to the Thames than to endeavour to get the additional water which they want from the Lea. I also know from sources of private information which were all brought out in my examination before the Committee on the East London bill last year, that the river Lea only supplied about 15,000,000 gallons a day for a considerable period during the summer of 1864, when 21,000,000 gallons, or something like that, from 19,000,000 to 21,000,000 gallons were actually being supplied, or were required, and every drop of water was pumped out of the Lea. The East London district had to be put on short commons for a good many days, and whatever was in the Lea, whether it was water pure, or water mixed with sewage or sewage itself, every drop was taken out, and it is the opinion of some who know the Lea well, that no material additional quantity of water could be obtained by impounding reservoirs beyond that which has already been taken; but however that may be, I find that it is cheaper to go to the Thames than to take it from the Lea, and therefore, in all the calculations which I am endeavouring to lay before the Commission I will assume that the additional water shall be taken from the Thames. In estimating the cost of obtaining water from the Thames by the existing companies, I have to ascertain, if I can, the expenses which are now incurred in pumping and in filtering. I have had some difficulty in doing that. It has been ordinarily assumed (I do not know upon what ground) that something like 80,000*l.* a year was spent by all the companies upon pumping, and in addition to that there was the filtering. There are public returns which are made every year to the town clerk of London, and deposited with him, all of which I have extracted, but they are given in such a way that nothing can be made of them, or scarcely anything. Earlier, when they were first given, there were some returns given in such detail that you could make something of them, but latterly they have been put in such a form that you can scarcely make anything of them, and for reasons which I daresay can be very well understood I have ton been able to obtain information from the companies themselves; I have therefore been obliged to go into a considerable amount of investigation in order to determine as nearly as I could the actual cost now incurred in pumping and in filtering. I find that the cost of

J. F. Bateman, Esq.

5 March 1868.

pumping has been given by various gentlemen, and that they all agree in almost every respect. Before Lord Robert Montagu's committee on the best means of disposing of the sewage, three or four years ago, two Cornish engineers appeared, and they gave the cost of raising the water at a price which I believe is equivalent when worked out to 20*s.* 10*d.* for each 1,000,000 gallons lifted 100 feet; they give 2*s.* 4*d.* and 2*s.* 6*d.* per 1,000 tons raised 50 feet, but I have worked it into a more convenient form, that the cost of 1,000,000 gallons lifted 100 feet is 20*s.* 10*d.* In the evidence which was given before you by Mr. Hawksley he gives the cost of pumping at a farthing per 1,000 gallons lifted 100 feet, and that works out to exactly the same figure, 20*s.* 10*d.* Then I happen to know from other sources which I cannot quite state, that the horse power in actual working, and in the case of the most economically worked engines in London, comes to 1*s.* an hour per horse power, and that worked out into the same figures comes to a fraction over 21*s.* per 1,000,000 gallons lifted 100 feet; so that if we take 21*s.* as the actual cost, with the best constructed engines, that will be the amount. Then I have compared that with the actual cost of working in the Liverpool works, where everything is done certainly as well as it can possibly be done, and there the cost of working, if coal were the same price which it is here, would be about 24*s.* or 25*s.* for the work done. I estimate 20*s.* 10*d.* I have taken also another engine which is supposed to be the crack engine in the country, and supposed to do the greatest amount of work, and in that case it would come to 31*s.* if the price of coal were the same; but they use very inferior material, and the duty done by each engine is so much less than the duty performed here, that that properly worked out brings it very much back to the same cost at which the work is performed in London, so that I think I have good ground for taking 21*s.* as the actual cost of raising the water.

6605. (*Mr. Harrison.*) Do you include interest on capital in that?—No, that is the net cost, it includes the ordinary repairs, but not the renewals of engines or the renewals of boilers, but just ordinary repairs. Messrs. West and Hocking, who gave evidence before Lord Robert Montagu's committee, gave it at that price. At the East London works it comes to 21*s.* 0½*d.*, or to 18*l.* 5*s.* per horse power per annum, for engines working night and day, that is excessively low.

6606. In answer to a question which I put to Mr. Quick, the engineer of the Southwark and Vauxhall Company, he stated that the cost is 13*s.* 10*d.* for raising 1,000,000 gallons 100 feet, and he promised when he was here to ascertain the exact fact from their books, this is what he states, including coals, oil, tallow, and wear and tear?—This sum appears to include the same items which are supposed to be included in the other. However, I have taken 21*s.* as the cost. I have before me a table only received this morning from the Liverpool Corporation Waterworks, from Mr. Duncan, who certainly does his work remarkably well, and where one of the engines is one of the best in the whole country, the Green Lane pumping engine; and there the average cost of lifting 1,000 gallons 100 feet high, which is the figure Mr. Hawkesley gave you, amounts to about three farthings, or about three times Mr. Hawkesley's price; but the Green Lane engine amounts to ·239 of a penny, and at the Windsor station, where there is also a very good pumping engine, it comes to ·289 of a penny, which is a trifle over a farthing, therefore I think 13*s.* 10*d.* is a very exceptional price; and considering that all the engines are not of that very superior description, and that that does not accord with any other information which I have received, I am not disposed to vary from the 21*s.* per 1,000,000 gallons raised 100 feet. There are a good many other instances, and which all come to about the same price, and I cannot think that that can be far off the actual cost on the average, but of course there may be exceptional cases. Then I had to ascertain the existing cost incurred in pumping and the existing cost of filtration. The cost of filtration varies in London from one-eighth of a penny per 1,000 gallons to a halfpenny per 1,000 gallons, and several of the larger companies work it at one-eighth of a penny per 1,000 gallons, and to two of the companies it costs a halfpenny or rather more than a halfpenny per 1,000 gallons. That is from evidence which has been given before the Commission, and I have therefore taken it at one-sixth of a penny all through, in all the calculations which I have made. I may say that one-eighth of a penny amounts to 19,000*l.* a year, for each 1,000,000 gallons, one-sixth of a penny amounts to 25,000*l.* a year, and a halfpenny amounts to 76,000*l.* a year, and I have taken one-sixth of a penny, which is 25,000*l.* a year. The cost of pumping and the cost of filtering to the existing companies for the amount of water which they at present deliver I have taken at 120,000*l.* a year, and I want to show my ground for doing that. The Chelsea, the Grand Junction, and the Southwark and Vauxhall companies in 1866, which is a year in which we have certain particulars before us which enable us to deduce conclusions, raised about 29,000,000 gallons a day, at a cost of 46,368*l.* per annum. All the companies drawing water from the Thames together with the Kent Company supplied at that time 52,000,000 gallons per day, and the East London and the New River together 42,000,000, making a total of 94,000,000. Then as a rule of three question, if 29,000,000 cost 46,500*l.* a year, 52,000,000, the quantity raised on the south side of the river, would amount to 83,300*l.* a year. The East London and the New River companies do their work at half the cost of the other companies, from reasons which I have already given, and at half that cost in proportion to the quantity raised it would come to 33,640*l.*, being a total of 116,940*l.* The present horse power employed in London by the existing companies is about 12,000. The cost per horse power of the actual power in use is 1*s.* a day of 24 hours for 365 days in the year, or 18*l.* 5*s.* per annum. It is difficult to determine how much may be actually in use throughout the whole period; but assuming one half to be in use, that would be 6,000 horse power in actual use, and at 18*l.* 5*s.* per horse power that would come to 108,000*l.* a year, and the filtering for 94,000,000 a day would be 20,000*l.* a year, making a total of 128,000*l.* a year for pumping and filtration. Then I have done this in order to be surer still. I have analyzed the average height of the lift of each of the companies with the quantity of water which they lift, and I find that it comes to 200 feet as nearly as possible the average lift, and that the horse power required for lifting that quantity constantly at work, namely, 95,000,000 gallons, which is the quantity that they have taken for the year 1866, is 4,000 horse power, and I have supposed that they will be all as good engines as the East London Company's; therefore allowing for the intermittent supply, the greater cost of keeping the different engines at work, in order to supply the various quantities in the course of the day, I have taken it in round numbers at 20*l.* per horse power, that is 80,000*l.* a year. Then I have added 2*l.* a year for wear and tear and renewals on the horse power actually in use, (not the whole horse power employed, but that which is actually in use to produce that result,) that is 8,000*l.* a year, and the filtering I have taken at 23,000*l.*, and that comes altogether to 111,000*l.* But two large companies do not do their filtering at that rate, it costs them beyond the allowance of 23,000*l.* an extra amount of 8,500*l.*, and adding that it comes to 119,500*l.* a year in round numbers. Therefore from those various data, which I have been obliged to work out in the best way I could, I have taken the actual working expenses of pumping and filtering at 120,000*l.* a year. I have been rather careful to give you the grounds on which I have arrived at this, because when that is capitalized at 25 years' purchase, as I shall have to capitalize it as representing money borrowed at 4 per cent., it is important that I should be quite right upon those figures. I have tried to obtain direct information, but have not been able to do so. Then I have esti-

mated as nearly as possible the cost to which the companies must be subject for getting an additional 35,000,000 gallons a day. Taking the New River first from the paper before his Grace, they require 5,600,000 gallons in order to make up the quantity which I assume will be required when 130,000,000 gallons in the whole is required. It requires 600 horse power first of all to do the work, and I know by experience that you cannot put down pumping engines with pumps and buildings and all the other et cæteras, and everything complete, for less than 100*l.* per horse power, that is 60,000*l.* The expense of filters, reservoirs, and land for 6,000,000 gallons a day would be 4,000*l.* per 1,000,000 gallons, and there again I must give you the ground of my calculation. I have taken out the cost of filters which I myself have constructed in various parts of the country, and I happen to know also the cost at which filters are constructed on a large scale for the waterworks of London, and I find that allowing for the amount of filters which must always be out of use for cleansing, and the extent of filters which must also be at work in order to meet the varying quantities, not only of the months of the year but of the days of the month, a low estimate for the cost of construction would be 3,000*l.* per 1,000,000 gallons upon the quantity of water actually filtered, and then I have to add 20 per cent. for irregularity, which comes to 600*l.*, and for the land about three quarters of an acre for each 1,000,000 gallons, which I put at 400*l.*, which it would be where you are pretty near towns, it may be more or less than that, but that makes a total of 4,000*l.* per 1,000,000 gallons. My own filters at Chester, for instance, cost 3,485*l.*; at Dumfries, where I took the actual basins of an old filter, and supplied them with new filtering media, the cost of doing that was 2,240*l.* per 1,000,000 gallons, and at Rathmines, near Dublin, including a receiving tank, it was 6,600*l.* per 1,000,000 gallons. I could give many other instances, but I believe I am right in taking on the average, including all attendant expenses belonging to the construction of filters, 4,000*l.* per 1,000,000 gallons. I must now draw the attention of the Commission also to another thing before you can see clearly how we have to estimate the cost of pumping. The water companies make a return to the registrar general, and in various other ways they give information, but they return to the registrar general a monthly account of the average daily quantity used in each month; and if the Commission will allow me I will hand in the following tables:—

TABLE showing the average daily Quantity of Water supplied by the London Water Companies during the years 1866 and 1867, and during the summer months of June, July, August, and September in each year. Compiled from the Returns made to the Registrar General.

J. F. Bateman, Esq.

5 March 1868.

From the first of these tables you will see the average daily quantity. The average quantity consumed in 1866 you will find was 95,000,000 gallons in round numbers, and in 1867, 98,600,000 gallons. In the summer months, June, July, August, and September, when the largest quantity was delivered, the average daily quantity was 101,270,157 gallons in 1866, and 105,480,791 in 1867, showing that the increase of 1867 over 1866 upon the average quantity of the year was 3,703,000 gallons per day, and in the four summer months, June, July, August, and September, it was 4,210,000 gallons a day of increase. If you will have the goodness to turn to the two latter tables you will see the monthly variation. In January, February, March, and April 1866, it varied from 88,427,211 gallons to 89,505,453 gallons per day on the average of those months. In July it rose to 102,778,210 gallons, in August to 105,234,979 gallons, and in September to 100,655,057, so that you will see that the variation is from 88,000,000 to 105,000,000 in round numbers, which is as nearly as possible 20 per cent. or 10 per cent. upon 95,000,000, which was the average of the whole year. You must therefore have engine power sufficient to provide not for the 95,000,000, but for 10 per cent. more than that, or else you will be short of engine power when your greatest demand comes. That, however, shows only the monthly variation, and you have also not only to provide engine power for an average supply of 105,000,000 odd, but you must have engine power for supplying the diurnal variation during the 30 days of the month. The consumption on the maximum day of the month will be very much more than the average of the month, and you must at least add 20 per cent. more for that, for the additional days in some of the months, so that you have to provide for the maximum monthly quantity, and for 20 per cent. more than that, in order to meet the day of greatest demand, and you have to take this all into consideration in determining the quantity of horse power which is to be put down.

I will now hand in tables showing the cost of procuring additional supplies from the Thames. (*See Appendix M* (2)).

THAMES SUPPLY.—1st Instalment.

Estimated outlay for works, and annual working expenses, capitalized at 25 years' purchase, for obtaining an additional 35,000,000 gallons daily from the Thames, making a total supply of 130,000,000 gallons daily.

The additional supply will probably be required by the several companies in the proportions given in the following Table:—

Name of Company.	Present Supply, 1866.	Additional Supply.	Total Supply.
	Gallons.	Gallons.	Gallons.
New River - -	23,000,000	5,600,000	28,600,000
East London -	19,300,000	7,300,000	26,600,000
Chelsea - -	8,000,000	1,150,000	9,150,000
Grand Junction -	8,250,000	4,350,000	12,600,000
West Middlesex -	8,700,000	4,600,000	13,300,000
Southwark and Vauxhall -	12,700,000	6,700,000	19,400,000
Lambeth - -	9,000,000	2,250,000	11,250,000
Kent - - -	6,050,000	3,050,000	9,100,000
Total - -	95,000,000	35,000,000	130,000,000

SUMMARY OF COST.

Company.	Additional Quantity of Water required.	Estimated Outlay in Works.	Estimated annual working Expenses.	Working Expenses capitalized at 25 years' purchase.	Total Cost, including annual working Expenses capitalized.
	Gallons.	£	£ s. d.	£	£
New River -	5,600,000	242,025	9,014 3 7	225,350	467,375
East London -	7,300,000	247,000	9,065 16 0	226,650	473,650

West Middlesex	4,350,000	118,530	7,528 15 7	188,225	306,755
Southwark and Vauxhall -	6,700,000	224,411	9,068 15 5	226,725	451,136
Lambeth	2,250,000	126,750	2,796 12 0	69,900	196,650
Kent -	3,050,000	159,020	3,790 15 9	94,775	253,795
Totals -	35,000,000	1,294,401	52,063 8 11	1,301,575	2,595,976

Annual working expenses of present (1866) supply of 95,000,000 gallons daily:—

Pumping and filtration - -	£120,000	
Payments to Thames Conservancy by five companies now drawing from Thames -	6,400	
New River Company, Payment to Lea Trustees - - -	£1,500	
Hertford sewage -	600	
	2,100	
East London Co., Payment to Lea Trustees - - -	2,000	
Present annual cost -	£130,500	Capitalized at 25 years = 3,262,500
Total cost of increasing supply from Thames to 130,000,000 gallons daily - - - - -		£5,858,476

THAMES SUPPLY.—2nd Instalment.

Estimated outlay for works, and annual working expenses, capitalized at 25 years' purchase, for obtaining a further additional supply of 40,000,000 gallons daily, increasing the supply to 170,000,000 gallons daily.

The additional supply will probably be required by the several companies in the proportions given in the following Table:—

Name of Company.	Present Supply, and first additional Supply as already apportioned.	Additional Supply now estimated for.	Total Supply.
	Gallons.	Gallons.	Gallons.
New River - -	28,600,000	8,580,000	37,180,000
East London -	26,600,000	7,980,000	34,580,000
Chelsea - -	9,150,000	2,835,000	11,985,000
Grand Junction -	13,300,000	3,990,000	17,290,000
West Middlesex -	12,600,000	3,780,000	16,380,000
Southwark and Vauxhall -	19,400,000	5,820,000	25,220,000
Lambeth - -	11,250,000	3,375,000	14,625,000
Kent - - -	9,100,000	3,640,000	12,740,000
Totals - -	130,000,000	40,000,000	170,000,000

SUMMARY OF COST.

Company.	Additional Quantity of Water required.	Estimated Outlay in Works.	Estimated annual working Expenses	Working Expenses capitalized at 25 years' purchase.	Total Cost, including annual working Expenses capitalized.

	£	Estimated at £	£	£	£
Present (1866) supply 95,000,000 gallons	—	130,500	3,262,500	—	3,262,500
130,000,000 gallons, or additional supply of 35,000,000 gallons	1,294,401	52,063	1,301,575	2,595,976	5,858,476
170,000,000 gallons, or further additional supply of 40,000,000 gallons	1,255,756 and 1,500,000 (store reservoirs.)	61,389	1,534,725	4,290,481	10,148,957
200,000,000 gallons, or further additional supply of 30,000,000 gallons	745,750	49,654	1,241,350	1,988,100	12,137,057
230,000,000 gallons, or further additional supply of 30,000,000 gallons	1,039,557	40,362	1,009,050	2,048,607	14,185,664
300,000,000 gallons, or further additional supply of 70,000,000 gallons, at same rate of cost as for preceding instalments, including additional store reservoirs	3,026,314	105,502	2,637,550	5,663,864	19,849,528

Without going through the whole detail of these tables, but taking the sizes of pipes according to the quantity required and the distances, supposing that the New River Company, for instance, which has not yet gone to the Thames, went to Sunbury, which is a spot just above Hampton, and which was the spot selected by the East London Company last year, and which would be the most convenient place for the New River Company to go to, I make the actual cost in outlay 242,000*l.* for the New River Company. Then as regards the annual working expenses, I have taken the average quantity of water lifted 270 feet, (which is the amount, including friction,) at 21*s.* per 1,000,000 gallons. I have taken the wear and tear of the horse

J. F. Bateman, Esq.

5 March 1868.

power actually in use at 2*l.* per horse power per annum, and the filtering at one-sixth of a penny per 1,000 gallons, and that makes 8,014*l.* as the annual working expenses. You must then add 1,000*l.*, which the New River Company will have to pay to the Thames Conservancy Board, as the amount which they would have to contribute, which was the price fixed for the East London Company last year, and it is the price which was paid in addition to the sum formerly paid by each of the other five companies. The East London Company was to pay 1,000*l.*, and I put down 1,000*l.* for the New River Company, that makes a total of 9,014*l.* I have capitalised that at 25 years' purchase, which represents money borrowed at 4 per cent., and that comes to 225,000*l.*, being a total of outlay and of annual expenses capitalised of 467,000*l.* I have worked out the outlay of the East London Company in the same way, and of the Chelsea Water Company, and all the others, and I find that the gross cost which will be incurred in outlay will be 1,294,401*l.*, and the working expenses, capitalised at 25 years' purchase, will be 1,301,575*l.*, making a total cost, including the annual working expenses capitalised, of 2,595,976*l.* Then I have to add the present working expenses as nearly as I can ascertain them. I have taken, for reasons which I have already explained, the pumping and filtration at 120,000*l.* a year; the payments to the Thames Conservaney by the five companies now drawing water from the Thames 6,400*l.* a year; the payment by the New River Company, 1,500*l.* to the Lea trustees, and the expenses of the Hertford sewage clarification, which is 600*l.* a year at least, making 2,100*l.*, and the payment to the Lea trustees by the East London Company 2,000*l.*, making the total annual expenses 130,500*l.*, which capitalised at 25 years' purchase comes to 3,262,500*l.*, showing a total of 5,858,476*l.*

6607. Will the water companies get relief from those payments which they are now liable to make to the Conservators of the Thames if they cease to take water?—I should think so.

6608. Are you not aware that upon the strength of that money the Conservancy Board are laying out a considerable amount of money upon the Thames?—I cannot answer that question, but I should think they would be doing so. It is paid in consideration of certain duties performed by the Conservators for the purpose of keeping the river pure.

6609. (*Sir J. Thwaites.*) But they are performing those duties, are they not?—Yes, but they are annual expenses, and the payment is in consideration of their annual expenditure for what they call scavenging the river, and as they will no longer have occasion to scavenge the river the expenses will not be incurred, and there will be no occasion to pay.

6610. (*Col. Harness.*) Are the Conservators borrowing money upon the strength of that payment?—I cannot answer that question, but they will not have borrowed as much as represents a payment of 6,200*l.* a year, or else they would have nothing left out of the annual payment if the whole was absorbed in interest to do the scavenging of the river with.

I have then considered that the Kent water, judging from the report of Dr. Frankland, is certainly not a desirable water to deliver to the inhabitants, and therefore I have supposed that the additional quantity of water which the Kent Company may require shall also be taken from the Thames, which is, in every way, by analysis, a superior water. The total cost, treated in this way, of obtaining 130,000,000 gallons in the whole from the Thames and the other existing sources, including the Kent supply as far as it now goes, is 5,858,476*l.* The cost of obtaining the same quantity of water from North Wales is 6,602,188*l.*, being a difference of 743,712*l.* against the Welsh scheme in money expenditure, exclusive of interest and other expenses during construction. If these be added the difference against the Welsh scheme (if no charges of the same kind be made against the Thames) will be 1,826,530*l.* When a total quantity of 170,000,000 gallons per day is required it will be nearly 600,000*l.* in favour of Wales, vide table, p. 389 of Evidence given 11th March 1868, Q. 6632. It therefore appears that at present, and for some years to come, it is cheaper to get a supply from the Thames and from the existing sources than from a distance. But a period will arrive at no great distance of time, say in something like 10 years from the present time, when, looking at it as a mere question of cost in pounds, shillings, and pence, it will be cheaper to bring it from Wales than it will to take it from the Thames. That is a period of four years only, or five at most, later than the period at which the works will be completed; and as I observed yesterday, we must always be at least five years ahead of the actual demand, in consequence of the time which is required for executing works of extension; therefore in seven or eight or ten years at most, looking forward to the works with which you must be always in advance, it will be a tie between Wales and the Thames, and if so, it is a tie between water of only one or two degrees of hardness, and water of 13 or 14 degrees of hardness, a difference which will certainly save to the inhabitants of London a sum equal to about 500,000*l.* a year, which is the representative of about twelve millions of money at 4 per cent.; on these figures it surely would be worth while going to that extra distance for the water. I must observe that in the estimate of the amount of money to be expended upon the Thames for supplying 170,000,000 gallons, I have added a sum for the cost of constructing reservoirs upon the Thames. Those have not been carefully estimated, but they have been guessed at by witnesses before you at about 800,000*l.* for reservoirs alone, to which is to be added a tunnel to Abingdon, and many other things, so that is an under-estimate of the whole cost. I have allowed for the whole expenditure which may be required 1,500,000*l.*; it may be 200,000*l.* or 300,000*l.* more or less. I have not gone particularly into it.

The scheme which I have laid before you is based upon a quantity of 230,000,000 gallons; if it were prepared for 300,000,000 gallons certain parts of the work would have to be enlarged. The district itself which is appropriated, without taking in any other districts which may be added to the scheme, will give 300,000,000 gallons if it is measured by 120 days of drought; but in order to convey 300,000,000 gallons those portions of the conduit which will be covered must be made rather larger, and in arranging the level at which the open conduit must be constructed it must be so adjusted that in passing under railways or roads it shall be sufficiently depressed to allow the addition of some couple of feet to the side walls, according to the sketch which I will show you (*producing a sketch and explaining the same*). Instead of 16 feet 6 inches, which I believe is the width of the covered conduit for the conveyance of 230,000,000 gallons, the conduit will have to be made 18 feet wide and 2 feet deeper, and the open conduit will have to be arranged with a view to raising the side walls, by the parts coloured purple, whenever the additional quantity is required. A 10 feet deep conduit, according to the shape which has been prepared, will convey 230,000,000 gallons, and with 2 feet added it will convey 300,000,000 gallons; that is the whole additional work as far as the open conduit is concerned, and the covered conduit, instead of being 16 feet 6 inches, will have to be made 18 inches wider than it would be for the conveyance of 230,000,000 gallons, and 2 feet deeper. An additional reservoir will have to be constructed for holding the increased quantity of water at Edgware, and additional syphons will have to be constructed. All that is required in the first instance is the enlargement of the covered portion of the conduit, and for that the additional cost is only 225,000*l.*

6611. What would it have cost if it had been made the full size originally?—225,000*l.* I am supposing now that you contemplate making it large enough for 300,000,000 gallons. The open watercourse does not require to be altered at all, when the time comes you

add a little bit at each side. Then the covered conduit would be required to be made of larger dimensions, and the difference between the cost of making it of dimensions sufficient for passing 230,000,000 gallons, and of dimensions sufficient to pass 300,000,000 gallons, with the same fall per mile, would be 225,000*l.*, to which there is 15 per cent. to be added, making as nearly as possible 250,000*l.* I will now hand in my estimate for the additional outlay for the supply of 300,000,000 gallons.

J. F. Bateman, Esq.

5 March 1868.

WELSH SCHEME.

Estimate of additional outlay if works laid out for a supply of 300,000,000 gallons per day instead of 230,000,000 gallons.

Main aqueduct from Marten Mere to Edgware.		
Covered aqueduct or tunnel (for particulars and estimate, see Appendix A R (1)) - -	£36,800	
Estimate for 230,000,000 gallons - - - - -	33,180	
Difference per mile -	£3,620	
Length 65 miles, at 3,620*l.* - - -		£225,300
Open aqueduct (for particulars and estimate, see Appendix A R (2))	£27,640	
Estimate for 230,000,000 gallons - - - - -	25,000	
Difference per mile -	£2,640	
Length 75½ miles, at 2,640*l.* - - -		199,320
		£424,620
Contingencies, 15 per cent. - - -		63,693
		£488,313
Syphons:		
Three additional lines of 4 feet pipes, 10,824*l.* × 3 = 32,472*l.* per mile.		
11½ miles, at 32,472*l.* =	£373,428	
River crossings, valves, &c. -	7,500	
	£380,928	
Contingencies, 5 per cent. -	19,046	
		399,974
		£888,287
Additional land, say - - - -		11,713
Branch aqueducts to join main aqueduct at Marten Mere:		
Branch aqueduct from Vyrnwy and Banw district as proposed will discharge 150,000,000 gallons daily if required by a little additional depth of water.		
Amount carried forward - - -		£900,000
Amount brought forward - - -		£900,000
Additional syphon pipes, 1 line:		
2 miles at 10,824*l.* per mile - -	£21,648	
River crossing, valves, &c. -	2,500	
	£24,148	
Contingencies, 5 per cent. - -	1,207	
	£25,355	
Branch aqueduct from Severn district to Marten Mere:		
Same section as proposed for Vyrnwy and Banw branch aqueduct would have to be adopted.		
Cost for open watercourse, per mile -	£20,100	
Cost of section estimated for - -	14,820	
Difference per mile	£5,280	
14½ miles, at 5,280*l.* -	76,560	
Cost of covered watercourse or tunnel, per mile -	£26,100	
Cost of section estimated for - -	24,000	
Difference per mile	£2,100	
7 miles, at 2,100*l.* -	14,700	
	£116,615	
Contingencies, 15 per cent. -	17,492	
		134,107
Additional reservoirs and works for collecting and storing water, say - -		150,000
		£1,184,107
Say £1,200,000		

6612. (*Mr. Harrison.*) Do you propose to make your covered conduit the full size in the first instance?—I think 230,000,000 gallons is a tolerable quantity, but I think it would be advisable to make it the full size for 300,000,000 gallons.

6613. Supposing you had to alter this covered conduit, how would you do that with the supply going on?—That would be a difficulty of course; probably you would have to make another conduit, and it would be better to have it made the full size in the first instance.

6614. As far as your covered conduit was concerned you could hardly alter it?—No, we should be obliged to make another.

6615. Assuming that ultimately you may have to supply the larger quantity, would it not be as well either to make the conduit of the full size in the first instance, or to make two culverts, one merely equal to 170,000,000 gallons in the first place, and afterwards to make a second one for the remaining quantity whenever it may be required?—Possibly the latter. They are very large things when they come to be 18 feet wide, but it would be much more costly.

With reference to a question which was asked me yesterday, as to what the rainfall of a minimum year was as compared with the mean rainfall, perhaps I may be allowed to put in the following statement. I have extracted from the Liverpool returns, which represent seven gauges and 14 years' observations, and from the Glasgow returns, which represent a good many years' observations, and from the Manchester waterworks returns, the proportion which a minimum year bears to the mean rainfall. That is perhaps rather important, and I will hand it in.

The witness delivered in the following table:

TABLE showing the minimum Rainfall at various Places, and the Proportion which it bears to the mean Rainfall of those Stations.

Stations.	No. of Years' Observations.	Minimum Rainfall.	Mean Rainfall.	Proportion of Minimum to mean Rainfall.
Liverpool, C.W.W.—Rivington.	14	34·78	45·14	77 per cent.
Glasgow, C.W.W.—Loch Katrine district.				
Bridge of Turk - -	14	39·00	59·2	66 „
Glen Finlas - - -	11	48·00	59·2	81 „
Glengyle - - -	14	65·5	92·0	71 „
Aberfoyle - - -	14	34·6	53·9	64 „
Ledard - - -	12	67·1	85·0	79 „
Ben Lomond - -	13	67·2	90·6	74 „
Average of Loch Katrine district.	—	53·57	73·3	73 „
Manchester, C.W.W.—				
Rhodes Wood - -	12	34·49	44·20	78 „
Woodhead - - -	12	40·33	48·83	84 „

The witness withdrew.

Adjourned to Wednesday next, at 12 o'clock.

Wednesday, 11th March 1868.

PRESENT:

HIS GRACE THE DUKE OF RICHMOND, K.G., IN THE CHAIR.

Sir JOHN THWAITES.
Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS, C.B.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

J. F. Bateman, Esq.

11 March 1868.

JOHN FREDERIC BATEMAN, Esq., further examined.

6616. (*Chairman.*) Will you kindly proceed with your evidence from the point at which you left off on Thursday last?—I wish to say a few words in further explanation of the evidence which I was giving just before I concluded on Thursday.

The following calculations will show the accumulating interest and expenses during the construction of works.

WELSH SUPPLY.

MEMORANDUM as to Interest on Outlay for Works during the time of their execution.

Time required from commencement of parliamentary proceedings to completion of works, as follows:

Preliminary investigation of country on line of aqueduct, surveys, sections, and Act of Parliament	1 year
Preparation of working drawings, arrangements for land, &c.	1 year
Execution of works from time of letting contracts to delivery of water to the existing centres of supply	5 years
	7 years

MEMORANDUM as to Time and Manner in which Outlay would be apportioned.

Reservoirs in Wales, and main and branch aqueducts would be in course of construction during the whole five years, and over this period the cost, estimated at 5,760,000*l.*, would be spread.

The service reservoirs at Edgware and aqueduct thence to Crouch End would be in course of construction during the last three years, and over this period the cost, estimated at 470,000*l.*, would also be spread.

The syphons on the branch and main aqueducts, and the pipes for connecting the scheme with the existing centres of supply, would be laid during the last two years, and over this period the estimated cost, 1,379,000, would also be spread. The total estimate for works, including land and contingencies, is in round numbers 7,600,000*l.*

Outlay:

1st year—Parliamentary plans and surveys, Act of Parliament, &c.		£50,000
2nd year—Preparation of contract drawings, arrangements for land, &c.		250,000
3rd year—$\frac{1}{5}$ of 5,760,000*l.* =	£1,152,000	
Superintendence	25,000	
		1,177,000
4th year—$\frac{1}{5}$ of 5,760,000*l.* =	1,152,000	
Superintendence	25,000	
		1,177,000
5th year—$\frac{1}{5}$ of 5,760,000*l.* =	1,152,000	
$\frac{1}{3}$ of 470,000*l.* = say	158,000	
Superintendence	28,000	
		1,338,000
6th year—$\frac{1}{5}$ of 5,760,000*l.* =	1,152,000	
$\frac{1}{3}$ of 470,000*l.* =	156,000	
$\frac{1}{2}$ of 1,370,000*l.* =	685,000	
Superintendence	40,000	
		2,033,000
7th year—$\frac{1}{5}$ of 5,760,000*l.* =	1,152,000	
$\frac{1}{3}$ of 470,000*l.* =	156,000	
$\frac{1}{2}$ of 1,370,000*l.* =	685,000	
Superintendence	40,000	
		2,033,000
		£8,058,000

Included in above for Act of Parliament, law, and engineering expenses, 458,000*l.* = 6 per cent. on 7,600,000*l.*

Interest at 4 per cent. per annum will be as follows:

Outlay of 1st year—	£50,000	Interest due at end of following year	£2,000
2nd year	250,000		
	50,000		
	2,000		
	302,000	Do.	12,080
3rd year	£302,000		
	12,080		
	1,177,000		
	1,491,080	Do.	59,643
4th year	£1,491,080		
	59,643		
	1,177,000		
	2,727,723	Do.	109,109
5th year	£2,727,723		
	109,109		
	1,338,000		
	4,174,832	Do.	166,993
6th year	£4,174,832		
	166,993		
	2,033,000		
	6,374,825	Do.	254,993
7th year, £2,033,000, half of which will bear interest and become due at end of year, 4 per cent. on say 1,000,000*l.* for half a year			20,000
Total amount of interest due and payable to end of 7th year, when works are to be finished and in a revenue producing condition			£624,818

WELSH SCHEME.

SUMMARY of Estimated Outlay for obtaining the Supply from Wales and distributing same to existing centres of supply, including interest of money and general expenses during construction of Works.

First instalment of 130,000,000 *gallons daily*—

Reservoirs and works for collecting and storing water in the Vyrnwy and Banw district, including land and contingencies	£489,882	
Branch aqueduct from river Banw to Marten Mere, including land and contingences	599,137	
		£1,089,019
Main aqueduct from Marten Mere to Service Reservoirs near Edgware (Syphon pipes—when required, capable of discharging 130,000,000 gallons daily)		5,453,359
Service reservoirs near Edgware, and distribution of water to the various districts		1,059,810
Cost of works		£7,602,188
General expenses, including Act of Parliament law and engineering expenses, 6 per cent. on 7,602,188*l.*	£458,000	
Interest on outlay during construction of works	624,818	
		1,082,818
		£8,685,006
Deduct value of property of companies which may be disposed of as soon as supply by gravitation is introduced		1,000,000
Total cost of obtaining first instalment of 130,000,000 gallons daily		£7,685,006
Amount carried forward		£7,685,006

Amount brought forward	-	£7,685,006
Second instalment of 40,000,000 *gallons daily additional—*		
Reservoirs and works for collecting and storing water in the river Severn proper district, including land and contingencies	£570,291	
Branch aqueduct to Marten Mere, including land and contingencies - - - - -	492,117	
Additional syphons on main aqueduct, from Marten Mere to Edgeware - - -	266,650	
Additional service reservoir near Edgeware, piping and other works for distribution of water to the various districts -	557,551	1,886,609
Total cost of obtaining a supply of 170,000,000 gallons daily - - - -		£9,571,615
Third instalment of 30,000,000 *gallons daily additional—*		
Additional syphons on main aqueduct from Marten Mere to Edgware - - - -	£133,324	
Additional mains and works for distribution of water - -	117,535	250,859
Total cost of obtaining a supply of 200,000,000 gallons daily - -		£9,822,474
Fourth instalment of 30,000,000 *gallons daily additional—*		
Additional syphons on main aqueduct from Marten Mere to Edgware - - - -	£133,324	
Additional service reservoir near Edgware, and works for distribution of water - -	444,225	577,549
Total cost of obtaining a supply of 230,000,000 gallons daily - - -		£10,400,023

In carrying out any new scheme it would probably require, even if one had the honour of starting the thing at once, and supposing there was no successful opposition, a year at least to prepare for and obtain an Act of Parliament; it would take at least another year to prepare the working drawings and specifications before the works could commence, and it would take five years to execute the works: that is seven years from the time at which any project could be seriously considered. Allowing for the previous time which might elapse, it would probably be eight or nine years from the present time before it could be considered possible that any scheme from a distant source could be brought into operation; but for the purpose of interest upon accumulating capital it would have to be taken from the time at which you commence the expenditure of money, and therefore beginning with a small amount of interest and with a gradually accumulating quantity as the money was being more rapidly spent, it would pass over a period of about seven years. I showed before the rate of progress at which the quantity of water demanded would probably proceed, and I fear I shall have to go over that a little to show you the probable period at which the water would be required, because upon that depends the comparison of the two outlays, for the purpose of showing at what period the cost of obtaining it by pumping from the Thames or from the Lea from the existing sources, and the cost of obtaining the quantity which will be required from Wales will be a tie, from which time of course gravitation works would be much cheaper than pumping works, and the comparison would be very much in favor of the Welsh scheme. At present the supply averages 32 gallons per head upon the gross population of the district supplied, measuring the number of the houses by the proportion of inhabitants to a house which obtains in the metropolitan districts. It so happens that the population measured in that way is just the amount of population within the metropolitan district commanded by the Board of Works, but a population of nearly 200,000 persons into whose houses the present companies carry their water, lies outside that metropolitan district; perhaps the whole of those are not supplied, but to whatever extent they are supplied, to that extent of course the population within the metropolitan board's jurisdiction are deficient in supply, and there is of course a very considerable number of people who have now no legitimate supply. The taking of water being voluntary, and the payment voluntary, there is no compulsion upon the people to take the water, and therefore there are many houses which are not legitimately supplied with water by the water companies. Allowing for that, and allowing for the great increase which it is alleged, and which it is feared by the existing companies will occur, as soon as a constant supply is given, (and I have no doubt it will increase, although probably by care it may be brought down to a proper legitimate amount in time, yet at first I have no doubt it will increase,) and taking into account also the high pressure which will be introduced and which will also increase the supply, I do not think it is safe to calculate upon less than 40 gallons a head. The 32 gallons now supplied are measured upon the gross population, and you would have to add to that amount the effect of constant supply which will increase the quantity, and you would have to add to that (if the works are carried out upon the principle of a commission being appointed and allowed to levy compulsory rates, and everybody therefore being in a condition to take the water,) the additional quantity which people now unsupplied with water would take, therefore I do not think it is safe to calculate upon less than 40 gallons a head if the system were carried out, as I think it ought to be carried out, of giving everybody a constant supply of water at high pressure.

J. F. Bateman, Esq.

11 March 1868.

6617. (*Sir J. Thwaites.*) Do you intend that quantity to include water used for manufacturing and other purposes?—Yes, it includes manufacturing purposes, public purposes, and everything else. The present population of London is about 3,100,000 persons—it has increased at the rate of 19 per cent. in the last 10 years—that is 1·9 per cent. per annum if it happened to be the average, but the average increase is 1·73 per cent. upon each year. Ten years hence, at the same rate of increase, the population would be rather more, but we will assume it at 3,700,000 persons. Ten years hence the average quantity of water, at 40 gallons per head per day, would be about 150,000,000 gallons daily, that is the average quantity. Then allowing 10 per cent. for the maximum variation above the mean, in the monthly means which are returned by the companies to the registrar general, the maximum quantity, or rather the average quantity of the summer months, because the summer months run very nearly the same, will be 165,000,000 gallons per day, that is within about 5,000,000 gallons per day of the maximum quantity which the companies have now the power of withdrawing from the Thames and from other sources. Perhaps I ought to allow them 180,000,000 for reasons which I will show afterwards, and in that case it would be within 15,000,000 gallons of the maximum quantity which the companies can now draw from the existing sources and from the Thames, allowing some addition which I will explain by and bye without the construction of storage reservoirs. At present the five Thames companies have the power of drawing each 20,000,000 gallons a day which makes 100,000,000. The East London company has acquired the power of drawing 10,000,000 gallons more, that would make 110,000,000 gallons, and if the New River and the Kent Companies were supposed to go to the Thames also they would probably get the power of drawing another 10,000,000 gallons which would make 120,000,000 gallons, and the East London and New River Company from their present sources, and the Kent from its present sources, the three combined

J. F. Bateman, Esq.

11 March 1868.

would draw about 50,000,000 gallons a day from other sources than the Thames, which makes a total of 170,000,000 gallons. Therefore if 170,000,000 gallons be considered as the maximum quantity, and that is the quantity which has been spoken to by various engineers who are interested in the Thames supply as the quantity which might be drawn from other sources before it was necessary to construct storage reservoirs upon the river Thames, one year more than 10, that is 11 years from the present time, would bring up the demand upon the Thames and upon the existing sources to the full extent to which they could obtain water without the construction of storage reservoirs. Then before they could take any further quantity they must have already constructed storage reservoirs.

6618. That is on the assumption, is it not, that no further quantity than the statutory limit could be taken without injuring the Thames?—I have allowed 120,000,000 gallons per day from the Thames before any reservoirs are needed.

6619. Is it your opinion that 120,000,000 gallons is the utmost that could be taken from the Thames without the storing process being resorted to?—I do not express any opinion upon that, because I have not specially considered the Thames, but I take the evidence which has been laid before the Commission, which is pretty much to this effect. Mr. Simpson, who is a very good authority upon that point, says that they can take 100,000,000 gallons, perhaps 120,000,000 gallons, and possibly 130,000,000 gallons from the Thames before storage reservoirs would be required, and that agrees with the evidence of other gentlemen which has been laid before the Commission; therefore I take that evidence in preference to expressing any opinion of my own upon that point. Then you will observe that if that is all they can take, or rather if that is the maximum quantity, the maximum quantity represents a greater quantity than the average, because they are not permitted by Act of Parliament to take on any one day more than a certain quantity, and the diurnal variation will probably be 20 per cent. greater than the average quantity throughout the year; therefore they must have constructed their storage reservoirs before they can get any quantity, say, more than 170,000,000 gallons, from all sources. The various estimates which have been given upon the cost of making those storage reservoirs entitle me to conclude that about a million and a half would be something like the cost of what it is considered would be required. Mr. Bailey Denton speaks of between 5,000,000*l.* and 6,000,000*l.* as being required for the purpose of purifying the water, and leaving the companies to pump the water as they do now. Mr. Beardmore speaks of 700,000*l.* or 800,000*l.* for the reservoirs, besides six miles of tunnel to Abingdon and other works which he does not estimate. I am endeavouring to estimate it as well as I can. I have allowed a million and a half upon the storage reservoirs and other works which would be required in the valley of the Thames, and that million and a half I have added to the expenditure required and the cost of pumping capitalized, in order to fix the cost at which any additional quantity beyond 130,000,000 gallons can be obtained. The expenditure which will be required by the water companies for obtaining 130,000,000 gallons a day is 5,858,476*l.*; that is to say, the additional cost in outlay, and the cost of working expenses, and the cost of raising 35,000,000 gallons more than their present supply, capitalized makes 5,858,476*l.*; and that is for 130,000,000 gallons on the average. Then before you can go beyond that quantity you have to add the expenditure for reservoirs which must be ready by the time you want them, and therefore it makes the total expenditure, before you can get more than 130,000,000 gallons, on the average 8,760,000*l.*

6620. What do you add for the reservoirs?—1,500,000*l.*; that is, the reservoirs, tunnels, land, and all the other works which would be necessary, and compensation, and every question connected with it. Before we can get 150,000,000 gallons, which would be the tie between Wales and the River Thames, we have to add 700,000*l.* upon works and 700,000*l.* which represents working expenses capitalized, making a total of 1,400,000*l.*, and those together bring up the figure to 8,760,000*l.*

6621. Do you mean working expenses plus that which is necessary for your scheme?—No, for obtaining 150,000,000 gallons from the Thames on the average of the year. You will have to expend first of all 5,858,476*l.* for bringing up the total supply to 130,000,000 gallons, then you have to expend 700,000*l.* in works for the further 20,000,000 gallons, and an additional amount of 700,000*l.* represents the working expenses, capitalizing the annual amount at 25 years. This makes a total of 1,400,000*l.* to be added to the expenditure upon reservoirs and other works of 1,500,000*l.*, making a total of 2,900,000*l.*, which, added to the other amount, makes a total of 8,760,000*l.* for 150,000,000 gallons a day.

6622. (*Sir B. Phillips.*) Is that in addition to the expenses already incurred?—That is in addition to all outlay already incurred; but that is capitalizing the present working expenses for the additional quantity, and estimating the cost to be incurred for obtaining the additional supply beyond what they are now supplying.

6623. You are assuming that in the next 10 years taking the average of 40 gallons of water per head, you will require 150,000,000 gallons for the use of the metropolis?—Yes.

6624. The present quantity is about 110,000,000 gallons, is it not?—In the summer months it is about that; it was about 95,000,000 gallons in 1866, on the average of the year, and 100,000,000 gallons last year.

6625. Then to produce that 150,000,000 gallons over the next 10 years, would the existing companies have to expend 8,760,000*l.*?—Yes, or an equivalent in working expenses. In addition to all their present outlay, after capitalizing the existing working expenses and the working expenses which will have to be incurred, and adding to that the outlay which will have to be incurred, it will cost them 8,760,000*l.*

6626. (*Sir J. Thwaites.*) Do I rightly understand that your contrast starts with the pumping expenditure of the existing companies?—Yes.

6627. And you hold in abeyance the mechanical arrangements for distribution in the metropolis apart from both schemes?—Yes.

6628. You take the cost of pumping at present which is in excess of that which you would require, because you bring your water to a level of 200 feet above high water?—270 feet.

6629. Therefore you would require less pumping?—Yes.

6630. Then you go on to calculate the cost of increasing the supply from the Thames and the increased pumping power necessary, and then you proceed still further to estimate the cost of forming reservoirs for the purposes of storing the floods?—Yes.

6631. And having continually to add the increased cost of pumping?—Yes.

6632. And the cost of the reservoirs with the different compensations, and every question of easement and so on, which brings up the cost on that side to 8,760,000*l.*?—That is so; that is merely the cost of an increased supply from the Thames. I have not yet gone into the question of obtaining it from Wales on the other side. I have now before me a table which I will hand in to the Commission, showing, on the basis which I have been explaining to the Commission the cost of obtaining from existing sources 130,000,000 gallons, 170,000,000 gallons, 200,000,000 gallons, 230,000,000 gallons, and 300,000,000 gallons a day, as contrasted with the cost of obtaining the same quantity from North Wales.

COMPARATIVE ESTIMATES of obtaining additional Supplies of Water from the existing Sources and from North Wales.

Quantity of Water per Day.	Cost from the Thames and existing Sources.	Cost from North Wales, including Interest, Superintendence, &c.	Difference in favour of	
			Existing Sources.	North Wales.
Gallons.	£	£	£	£
130,000,000	5,858,476	7,685,006	1,826,530	—
170,000,000	10,148,957	9,571,615	—	577,342
200,000,000	12,137,057	9,822,474	—	2,314,583
230,000,000	14,185,664	10,400,023	—	3,785,641

NOTE.—In the above estimate 1,000,000*l.* is deducted from the cost of the Welsh scheme as the value of the property of the companies to be released and disposed of on the introduction of a supply from Wales.

If a supply of 300,000,000 gallons daily be contemplated the comparison will be as follows:

From the Thames and existing sources -	£ 19,849,528
From North Wales - - -	11,600,023
Difference in favour of North Wales -	£ 8,249,505

The first quantity, 130,000,000 gallons would be obtained from the Thames for 5,858,476*l.*; the cost of obtaining that quantity from Wales, adding all the interest of the money which is to be expended and the working expenses during its construction and so on, would be 7,865,006*l.*, being a difference of 1,826,530*l.* in favour of the existing sources. That quantity of water will probably be required in something like seven or eight years from the present time, that is as soon as the new works from Wales could be executed, and before much additional quantity from Wales beyond 130,000,000 gallons could be supplied it would be necessary to construct the second branch of the Welsh works, which would give a large additional, in fact the full additional quantity of water with reference to the storage power and the full size of the conduits everywhere except where syphons were required. I have shown the Commission that before the water from the existing sources could get beyond that 150,000,000 or 160,000,000 gallons, the companies must have laid out 1,500,000*l.* in the valley of the Thames, so that when 170,000,000 gallons were required the state of the case would be this, that from the existing sources it would cost 10,149,000 in round numbers, and from Wales 9,571,000*l.* being a difference in favour of Wales at that time of 577,000*l.* and odd. That is at a period distant from the present time, probably about 12 or 13 years. The tie is in about 11 years, and when it comes to about 11 years from the present time, which would be only three or four years after the works could be possibly executed, it is as cheap to obtain water from Wales, if the whole scheme were laid out on the scale of 230,000,000 gallons, as it is to obtain water from the existing sources.

6633. (*Sir B. Phillips.*) Is 10,000,000*l.* your maximum calculation for bringing 170,000,000 gallons from Wales?—Yes, in round numbers, and including the conveying of that water to the higher service reservoirs of the existing companies, to produce the necessary connection with the existing systems.

6634. Would that 10,000,000*l.* include the interest of the unproductive capital during the time of making these works?—Yes, till the first instalment of water is supplied, not after that.

6635. You say that to supply 170,000,000 gallons of water to London, after all the calculation you have made, would cost about 10,149,000*l.*?—Yes.

6636. And consequently the question of cost as between the two is pretty near equal?—They are not far different. I have taken credit in the Welsh supply for 1,000,000*l.* sterling in respect of the pumps, engines, land, &e., which would be available for sale, and be no longer used or necessary for the pumping establishments, they being sold and yielding a million sterling.

6637. Then under all circumstances, looking at the extreme calculation of 40 gallons per head per diem in London, and the increased population within ten years, you have a balance in your favour of 20,000,000 gallons over and above what you think you will require for the absolute supply of London?—Yes. *J. F. Bateman, Esq.* 11 March 1868.

6638. You were first speaking of the cost of 130,000,000 gallons; you are now speaking of the cost of 170,000,000 gallons?—Yes. The tie between the one and the other would be in about 11 or 12 years; that would depend upon the increase in the quantity of water.

6639. As a set-off, do you propose to do anything with the extra 20,000,000, looking at it as a money question?—Yes; 20,000,000 gallons, if it could be sold on the way at as low a price as 3*d.* per 1,000 gallons, would be worth 90,000*l.* a year, which would represent something more than 2,000,000*l.* sterling. I might deduct that from that the cost of bringing it from Wales. I doubt whether in that time you would sell as much as 20,000,000 gallons, but I think it is very likely you would sell 10,000,000 gallons. Birmingham is within 10 miles of the line of conduit. Birmingham has at present a very bad and indifferent supply. There are 300,000 people in the Birmingham district who may be said to be indifferently supplied. Probably 200,000 of the whole population of the Birmingham and Wolverhampton district are well supplied at present, although they have to raise the water to a great height. As we pass Birmingham the conduit would be something like 370 or 380 feet above the level of the sea, and therefore very little short of the highest houses in Birmingham. I do not think that Birmingham can be higher than that, or very little higher than perhaps 400 feet. Therefore there would be no great height to lift the water, and no great distance to carry it, and 3*d.* per 1,000 gallons would be a very low price; and if 10,000,000 gallons were sold at Birmingham and other contiguous places, that would represent 45,000*l.* a year.

6640. (*Mr. Harrison.*) What would be the distance of the conduit from Birmingham?—10 miles.

6641. (*Sir B. Phillips.*) Could not you produce the 150,000,000 gallons at a proportionately lower cost?—A little lower cost. This estimate goes on the basis of an ultimate quantity of 230,000,000 gallons a day; and after the conduit is once made, it does for 230,000,000 gallons without any further expense connected with the conduit, with the exception of additional syphon pipes across the valleys from time to time, as they are required. Therefore nearly the whole cost of the ultimate supply is incurred in the first instance.

6642. Supposing your Welsh water to be a desirable supply for certain purposes to London, you would not propose to do away with the use of the Thames water entirely, would you?—Yes, entirely; you can get the Welsh water cheaper than the Thames water from the point at which the two tie. If you were to continue taking any part of the supply from the Thames, you would be keeping property tied up which might be disposed of, and you would be keeping up the expenses of pumping and filtering, and all the attendant expenses of working the existing system, which might be done away with.

6643. Do you think it would be desirable that a city like London, with 3,100,000 people, with a prospect of a very large increase in the next 10 years, should rely wholly and solely for its water upon a district 200 miles away?—I see no difficulty about it. I do not see that it would be impolitic. The other day I showed the position in which the service reservoirs at Stanmore might be constructed, and there you might make store reservoirs which would hold, as I have already estimated, two or three weeks supply, and I have also shown that the land there is so well situated that you may take almost any reasonable amount. You may get two or three months' supply for London independently of the reservoirs in Wales, at a distance of about 8½ miles from Hyde Park. I think that that is a safer supply for the

J. F. Bateman, Esq.

11 March 1868.

city of London in case of any difficulty than the Hampton or Thames Ditton pumping stations. It is nearer, it is more secure from difficulty and from danger, and there you have the water stored up almost within gunshot.

6644. Do you think, looking at it in the latter point of view, that the public would be quite as satisfied that they should be dependent entirely for a supply of water to a city like London upon water that they receive from a distance of 200 miles?—I do not think that the public would ever trouble their heads about it. If they got good water day by day they would never inquire where it came from. It is a matter for the Commission to consider rather than the public, for as to the policy I am sure they would not consider it. Glasgow gets its water from a place 35 miles off, Manchester from about 20 miles, Madrid from 40 or 50 miles, and Paris is going to take its water from 130 or 140 miles. Madrid and Paris are much more liable to have their conduits disturbed than we are, I hope, in this country.

The cost of 200,000,000 gallons from the existing sources would be 12,137,000*l.*, and from Wales 9,800,000*l.* in round numbers, being a difference in favour of Wales of 2,300,000*l.* Then 230,000,000 gallons would cost 14,200,000*l.* in round numbers from the existing sources, and 10,400,000*l.* from Wales, being a difference of 3,785,000*l.* in favour of Wales. I may observe that in all the above estimates 1,000,000*l.* is deducted in respect of the property of the existing companies which would be realized, and which might be sold after the first introduction of the water from Wales. If a supply of 300,000,000 gallons daily were to be contemplated, and the works were constructed with a view to that from the commencement, it would entail an additional cost of only about 500,000*l.* upon the whole undertaking, because the district for which the reservoirs were laid out would yield 300,000,000 gallons, and the conduit would only require in the covered parts to be made a little larger, and in the uncovered parts a little bit to be added to each side of the side walls, which would give you the full quantity, and additional syphon pipes. The contrast would then be that if 300,000,000 had to be taken from the existing sources, the outlay would be nearly 20,000,000*l.*, but if taken from North Wales 11,600,000*l.*, the difference upon that quantity in favour of Wales being 8,250,000*l.*

6645. You state, do you not, that the cost of 170,000,000 gallons in London from existing sources would be something like 10,149,000?—Yes.

6646. And the cost of 200,000,000 gallons would be 12,137,000*l.*, that is a difference of 2,000,000*l.*?—Yes.

6647. Will you state how it is that it should cost 2,000,000*l.* for the additional 30,000,000 gallons per day deliverable from the London supplies, and only 250,000*l.* for the same additional amount coming from Wales, because you say that the supply from Wales of 170,000,000 gallons cost 9,570,000*l.*, and the cost of the production of 200,000,000 from Wales is only 9,800,000*l.*, which makes only a difference of 250,000*l.* as between 170,000,000 and 200,000,000 gallons?—The difference is in the difference of the two systems. In bringing the water from Wales you have to construct your aqueduct upon a scale equal to the conveyance of the ultimate quantity of water that you are going to bring, therefore you have to make it a great deal larger than is necessary in the first instance, because it cannot be conveniently added to afterwards. After the reservoirs are once constructed and the branch aqueduct up to the northern district which would be equivalent to 150,000,000 gallons, the only additional cost which you would have to incur would be the construction of the reservoir in the green district on the map, and that branch to bring the water down to the main aqueduct, and additional syphon pipes across the rivers Severn and Stour which are the only rivers which you have to cross. The difference of cost is only 250,000*l.*, and I can give you the figures upon which those amounts are arrived at. You are taking 170,000,000 and 200,000,000 gallons deliverable from the Welsh source. The cost is simply this, that the whole works after you have got 150,000,000 or 170,000,000 gallons are then upon a scale capable of delivering 250,000,000 gallons with the exception of the syphon pipes across the intervening valleys, and the pipes to communicate betwen the service reservoirs near Edgware and the existing reservoirs of the existing companies. The cost of the syphon pipes across the valleys would be 133,000*l.*, and the cost of the additional mains and the additional service reservoirs to communicate with the existing district would be 117,000*l.*, 250,859*l.* altogether. In pumping that additional quantity from the Thames you have to get additional engines, and you have to lay down additional mains and to incur the annual cost of filtering and raising the water.

6648. In the construction of your project, would you recommend the production of the smaller or the larger quantity of water; would you say that we should be satisfied and that the machinery should be so constructed that 170,000,000 should be the maximum quantity, or that we should be able to take 300,000,000 gallons?—I certainly would not recommend you to take 170,000,000 gallons, but only you might fairly consider the propriety of taking the larger quantity, because comparing 300,000,000 gallons with 230,000,000 or 250,000,000 gallons, the 300,000,000 gallons would only cost you about 500,000*l.* more.

6949. But if we are to borrow the money, that at 4 per cent. would be equal to 20,000*l.* a year?—Yes.

6650. As you say that there might be some difficulty in getting rid for some considerable time of the additional 20,000 gallons a day which you propose by the smaller quantity, what should we do with the much larger quantity for many years to come?—That could not make it very expensive, because if you never sold more than one-half of what the 500,000*l.* would procure, it would be only 250,000*l.*, of which the interest would be about 10,000*l.* a year. If you look at the table you will notice that as to the 170,000,000 gallons, the cost is in favour of the Welsh scheme, and in 12 or 13 years it is in favour of the Welsh scheme if you do not sell any of the surplus quantity. If you sell the surplus quantity of water you can make more than the interest upon 300,000*l.* for the additional expenditure which might be required. But I think that is entirely a matter of policy. I think that 200,000,000 or 250,000,000 gallons would last you a very long time.

6651. (*Mr. Harrison.*) Your calculation is entirely based upon the assumption that 40 gallons per head will be necessary?—Yes, but that 40 gallons per head is taking only the population within the metropolitan district; there is a large surrounding district which is in fact rejected in that calculation.

6652. Supposing views have been expressed before this Commission by many of the leading engineers connected with waterworks in London, or I think by all of them, that 30 gallons per head, even with a constant supply, would be sufficient, then 300,000,000 gallons would be just equal to the requirements of 10,000,000 of population?—Yes.

6653. And of course if their views are right, that would require a deduction of just 25 per cent. in all your calculations?—Hardly that, because if you make it nett upon the requirements of the population in London, you would have no surplus to sell upon your way.

6654. Taking London alone, of course the difference between 30 and 40 gallons, which is 25 per cent. in the gross calculation, makes a very important item?—Yes, no doubt. They are now using more than 30 gallons, and I think there cannot be a doubt about the quantity increasing, if you only look at it as it ought to be looked at.

6655. I was taking the evidence given by gentlemen who have been before this Commission, that even under a constant supply, and under such supervision, by a water police, as they suppose would be adopted, the increase in consumption would be nil from that cause?—It never has been, and I am quite satisfied,

and they themselves admit it, that with the increased habits of cleanliness and luxury which have been introduced, and baths and waterclosets and so on, there will be a much larger supply of water required than there has hitherto been. Mr. Simpson himself admitted that he takes 30 gallons now, whereas he used to take 20 gallons only, and it has gone up to 50 gallons in Glasgow. No doubt it is wastefully used there, but in every case the consumption of water is regularly increasing, and if you take the past experience of London, and merely estimate the supply of water in future at the same rate as it has been going on, you will find that it increases about 3 per cent. per annum, much more rapidly than the population. The population increases at the rate of 1·73 per cent., and the consumption of water increases 3 per cent. per annum.

One other point I should like to observe upon before I go further, and that is the cost of raising 1,000,000 gallons. A letter was handed me on the last occasion from Mr. Quick, stating that his estimate was 13*s.* 10*d.* per 1,000,000 gallons raised 100 feet, but that, I think, does not include wages. It is so different from anybody else's estimate that I am quite sure there is something omitted.

6657. He says "I find the cost of raising 1,000 "gallons of water 100 feet high, is between one-sixth "and one-seventh of a penny, or 13*s.* 10*d.* per 1,000,000 "gallons, including coals, oil, tallow, wear and tear, "&c." The cost of raising it includes wages as a primary charge, and it does not follow that because he has not put it down specifically he has not included it?—I have here the returns made every year to the town clerk of London by the various water companies. The one I have before me is that of the Grand Junction Company, which is one of the companies of which Mr. Quick is engineer. Up to the year 1862 inclusive, there was this return, "Repairs of works and "premises, filter-bed charges, oil and other working "expenses," under one item, and there was a second item, "Directors, auditors, office, salaries and office "charges," that was the way in which the returns were made up for all the years from 1853 to 1862 inclusive. I will take the three or four last years. In 1859 the repairs of works and filter-bed charges and working expenses were 11,700*l.*, and another item, which did not include men's wages, was 5,400*l.* In 1861 the first item was 12,500*l.* odd, and the second item 5,500*l.* odd. In 1862 it was 11,700*l.* and 5,550*l.* In 1863 the return was made differently, and it was put "Repairs of works and premises;" it was the same as far as the first item was concerned, but the second item had added to it "and men's wages." Then the first item which evidently included men's wages before fell from 11,700*l.* in 1862, and 12,500*l.* in 1861, to 7,800*l.* in 1863, and 9,200*l.* in 1864; the second item which then included men's wages jumping up from 5,500*l.* to 10,200*l.* and 10,500*l.* If you take the last year, 1866, for the Grand Junction Company, under the item "Repairs of works and premises, filter-bed charges, coals, and other working expenses," the cost was 10,647*l.* Then if you deduct filtration, which Mr. Quick does at one-eighth of a penny, upon 1,000 gallons, that leaves 8,984*l.* That water has to be raised about 250 feet at the Grand Junction, and it comes to 22*s.* 6*d.* per 1,000,000 gallons raised 100 feet. There must be some mistake about that 13*s.* 10*d.* Now I will give the cost at various other places. In the old Manchester Waterworks at the Gorton pumping engine, which was a capital engine, made by the Hayle Foundry Company, but which was superseded when I brought the water from the hills, the cost of raising 1,000,000 gallons 100 feet was 31*s.* 7*d.* I know as a fact that in the East London Waterworks, where Mr. Greaves works very economically, it costs him 21*s.* 0½*d.* Mr. Hawskley, in his evidence before you, gives it at a farthing per 1,000 gallons lifted 100 feet, which is equivalent to 20*s.* 10*d.* per 1,000,000 gallons raised 100 feet. Mr. West and Mr. Hocking, Cornish engineers, gave all the particulars of their estimate two or three years ago before the Select Committee on sewage, Lord Robert Montagu's committee, and they give it exactly as Mr. Hawksley gives it, 20*s.* 10*d.* per 1,000,000 gallons. In Liverpool where coals are very much cheaper than they are in London, and where Mr. Duncan is certainly as economical as anybody I know, the best engine, which is the Green Lane pumping engine, does the same amount of work at 19*s.* 11*d.*; the Windsor engine, raising a large quantity of water at 24*s.* 1*d.*, and the Audley Street engine at 23*s.* 5*d.* I could give many other cases, but I think those are enough to show that in taking 21*s.*, which I did, as the cost of raising 1,000,000 gallons 100 feet, I was taking rather a low sum upon the best engines in the country, and I cannot help thinking that there must be some mistake, either wages have been omitted or there must be some other mistake in Mr. Quick's statement of 13*s.* 10*d.*, as in the Grand Junction it does cost, according to the returns made by the company, 22*s.* 6*d.*

6657. (*Chairman.*) Will you now proceed with the next branch of the evidence you wish to lay before the Commission?—With regard to insufficiency of rain, which was one of the objections to my system, I think I must have established that there is plenty of rain, and sufficient storage in the Welsh district. Then the question comes as to coloured matter. I think I have referred before to the fact that with regard to Loch Katrine, which receives the water of the hills above where the entire drainage is a peat-covered district, that all the water which falls into the loch is the colour of dark coffee when seen in bulk, and yet the effect of the oxidation and bleaching which takes place in the loch itself is such that the water, although not absolutely colourless at certain seasons of the year, yet for a large portion of the year is absolutely colourless, and in autumn and the late summer months, when heavy floods after bad weather take place, it is almost colourless, and that it is so entirely from the effect of exposure in the basin of the loch itself. The length of Loch Katrine is about seven or eight miles, the water is taken at about one-third the distance down, at about 2½ miles from the head where the river Gyle runs into it as brown as coffee, and not a mile above Strowan burn, which is a browner stream even than the Gyle, and every other little stream running into it being at certain seasons of the year charged with colouring matter. There, certainly, the effect of deprivation of colour is almost complete, and for a large portion of the year the water is absolutely as pure and as colourless as a water can be. The effect in the Welsh reservoirs must certainly be the same, especially when I point this out to you. First of all, the drainage ground of the country above those reservoirs is not covered by heather and peat by any means to the same extent to which the Loch Katrine district is. The Llanwddyn reservoir which is the one on the north, is, I think, about six miles long. The water will be drawn from the lower end, the principal feeder coming from a considerable distance above there, and therefore the water will be drawn at a distance very much greater from the point at which the turbid water comes in than it is at Loch Katrine. The large reservoirs in the lower part of the same district are also of very considerable length. The Trefeglwys reservoir, which is a large reservoir on the southern portion of the drainage, is about four miles long, and more than two miles from any place where the water would be received from the natural feeders of that lake, and more than a mile below the point at which it is proposed to divert the river Carno into it. Bala Lake is about four miles long, and it is a great deal shorter than the Llanwddyn reservoir; it is not equal in length to those reservoirs, and it is not more than three-quarters the length of the Trefeglwys reservoir, and yet Bala Lake, which receives exactly the same character of water, is also almost absolutely colourless. The Manchester water is by subsidence in reservoirs also bleached to a considerable extent, and although a system of separation is carried out there which enables them to carry the water in a pure condition only, yet there also very considerable decoloration takes place in

J. F. Bateman, Esq.

11 March 1868.

the reservoir. I mean that the red colour is taken out of the water very much indeed by exposure. But I might refer you to the evidence which was given before you in which the river Don below Sheffield, and the river Irwell between Manchester and Warrington, were adduced as instances to show how much running water was deprived of colour, but there was one special instance, namely the river at Loughborough, below Leicester. Loughborough is about eight or nine miles below Leicester. At Leicester the water was described as being as black as ink, that nothing could live in it, that the smell was objectionable, and that in every respect it was as bad as could be, but by the time it got to Loughborough, eight or nine miles lower down, it was entirely restored to its pristine condition, fish were swimming in it, and you could see every pebble at the bottom. The time occupied in flowing from one place to another, at the rate of about a mile and a quarter, which is the usual speed of those rivers, would be only six or seven hours, and yet water as black as ink at Leicester was at Loughborough restored by mere exposure to the air, and by running in the river, to its pristine condition. The water from Wales would not only be exposed for a longer period than that, and would travel a greater distance in reservoirs or lakes, where it would be allowed to subside and be exposed for a long time to the action of the atmosphere, to the sun and the air, but it would have to run about 173 miles, in an open channel for a large portion of the distance, before it reached the reservoirs near Stanmore, and it would occupy something like 140 or 150 hours in doing that instead of six or seven hours, which is all that is required in order to convert a black stream into a pure one between Leicester and Loughborough. I think I hardly need pursue that subject further. The water will be as pure water, if not purer in point of colour than that which is delivered at Glasgow, and there is no Glasgow man who does not speak in the greatest possible praise of Loch Katrine water. And it would not require filtration, because everything of an objectionable character would subside, and the water would be delivered, as it is in Glasgow from Loch Katrine, in a perfectly pure condition.

6658. (*Sir B. Phillips.*) Do you say that from the Welsh district to London it will take 140 hours?—It will run at the rate of a mile and a half an hour, and it is 173 miles from the reservoir to Stanmore.

6659. (*Mr. Prestwich.*) Do you know how many days in the year they have that clean-coloured water in Glasgow?—It can hardly ever be said to be discoloured; there is the palest possible straw-tint in a large quantity; in a bath, for instance, in the autumn months, but if you see it in a glass, or in a bottle upon the table, it is perfectly colourless; it is only when you see it at a depth of two or three feet that there is any colour at all in the Loch Katrine water.

6660. Still that shows that there is a small quantity, although it is but a small quantity, of peaty matter floating in the water?—I do not dispute that, but it is not to an objectionable extent. Then you must consider the circumstance that nearly the whole water which Loch Katrine receives when it flows in is coloured, and the conduit is wholly covered from Loch Katrine to Glasgow, and it is therefore never exposed to the atmosphere or to the light after it once leaves Loch Katrine, which is a very important difference.

6661. (*Sir J. Thwaites.*) The water in the loch itself is perfectly pure, is it not?—Yes. I was there in September last year after very heavy rain when the water was at its worst colour. I never saw it so bad. I laid down, when I made the entrance basin at the mouth of the tunnel from Loch Katrine, a layer of white quartz pebbles in order to show the brilliancy of the water; those which were there in about four feet depth of water and some fresh ones which I threw in were changed at that depth to the palest possible straw colour, and that was all the discoloration that took place; at a foot deep, or two feet, or even three feet deep, you would not have been able to detect any colour at all.

6662. Is there anything special in the Manchester gathering ground to add colouring matter to the water?—Yes, there is a large quantity of peat in the Manchester water which flows into the reservoirs, but all the discoloured water is stored in separate reservoirs, and the pure uncoloured water and the spring water is either taken direct to Manchester, or stored in other reservoirs; but a portion of that which is discoloured water after being stored for a time becomes so pure that it is also taken to Manchester if it is required. The Manchester water is very much in the condition of that Glasgow water; there is occasionally a slight tint in it, but it ought not to be so; it is merely mismanagement if there is any colour whatever in the water at Manchester. There was one gentleman who said that the water was so much discoloured in Manchester that they actually used coloured tumblers to disguise it. I am afraid my friend who stated that must have been himself deceived, and I can only account for such an extraordinary statement by this fact, that in the refreshment rooms of the railway stations in Manchester and one or two of the hotels they use hock bottles for drinking water. I was in a refreshment room shortly after that statement was made, and I said, "Why do "you use those dark coloured bottles? Is it because "the water is so bad a colour?" "Oh, dear no, sir," they said, "We will draw you a little." They did so, and I perceived no colour in it, and I said, "Why "do you use those bottles?" They said, "It is "because they are cheap, and if they break it does "not signify much." And, besides, dark-coloured bottles are considered to keep water cooler in summer. I do not think a coloured tumbler was ever used in Manchester—except it may be an ornamental Berlin glass one—not as a common thing; certainly it is an entire mistake.

Another point which was made a matter of objection to the Welsh scheme was that there would be mischievous effects produced from the River Severn by loss of scour. That is a point of some importance, and I have made some calculations upon what the effect of the abstraction of the water would be. We shall interfere more or less with the water flowing from about 130,000 acres, which will supply 250,000,000 gallons a day; that is exactly one-twentieth of the whole acreage of the River Severn down to Gloucester, which is 2,600,000 acres. That is all we should interfere with when we came to take that quantity of water, but allowing for the great amount of water which would fall upon the mountain district as compared with the lower district, we may assume that if we bottled the whole of the water, and kept it back, it would be probably about one-fifteenth of the whole. But then we only take 40 inches out of 61 or 62 inches, which is the average amount of rain as I showed the other day; so that we should only interfere, if we even bottled the whole of it up, with two-thirds of the water coming from 130,000 acres. That would be about one-twenty-second or one-twenty-third part of the whole, but for a long time we should not take more than half of that. I have endeavoured to ascertain what the maximum flood would be below Gloucester, or at Gloucester exclusive of the tide; I cannot get a return as to the quantity of water in a flood there, but the evidence of one or two witnesses before you is that the maximum flood in the Thames is 25,000,000,000 gallons per day, and that is equivalent to 1·73 cubic feet per minute from each acre of drainage ground. I have assumed that the Severn floods would be two cubic feet per minute from each acre because it is a more precipitous and more mountainous district in the upper parts; I had occasion in investigating the inundations in the river Shannon for the Government some years ago, to ascertain what was the maximum flood to be provided for in all the rivers in the basin of the Shannon, and from information which was received from Mr. Forsyth, the engineer of the Board of Works, who had paid

much attention to the subject, and from my own measurement of the maximum floods in several parts of the Shannon, I found that 1 foot per minute from each acre is a very considerable flood, and that there is no river falling into the Shannon even where the volume of the flood is not checked by any lakes, which very materially modifies the amount of flood—there is no river which sends down more than 1·54 cubic feet per minute from each acre of ground, so that a flood of 1·73 feet from so large an area is a very considerable flood. I could give many instances of floods being very much larger than that from small areas, but not over so large an area as this. Taking it, however, at two feet per minute from each acre, the flood at Gloucester where it enters what may be considered the tide-way added to the quantity of water which the tide itself holds up, and which runs out at every tide, would be about from $\frac{1}{40}$th to $\frac{1}{50}$th part of the whole amount of the water in the estuary above Sharpness point. I have endeavoured to ascertain the quantity of water in the estuary by taking sections and by taking the rise of the tide and the fall of the tide, and I have ascertained from information the velocity at which the water runs past Sharpness point, and I have taken the quantity of water running up and down in each tide, and that is the result. There is a very small amount of traffic upon that part of the river which lies above Sharpness point. At Sharpness point the tide rises 32 feet 6 inches. Nothing but a few barges go up from there to Tewkesbury, a few sea-going vessels of about 150 tons burthen go up as far as Newnham, and all the rest of the traffic is carried on by the Gloucester and Berkeley canal, a ship canal constructed expressly for the purpose of avoiding the difficulties of the estuary in that portion of it; and I ascertained from information upon the spot also that one of the greatest difficulties which they have to contend with is the excessive floods which occasionally come down, that a moderate flood does them good, but that an excessive flood following upon the ebb-tide disturbs the channel so much that a bad naver gation is the consequence. That is quite consistent with what one knows and observes in other parts of the country, and therefore, I cannot think that the abstraction of so small a quantity of water as we shall abstract, will produce any mischievous effects upon the upper part of the estuary of the river Severn. I give that opinion for what it is worth. I can only express it as an opinion; I cannot prove it as I have endeavoured to prove all my other statements.

6663. It was stated in evidence that the advantage of those floods was to prevent the silting up of the mouth of the river, which would be the result if you abstracted that large quantity of water?—There is no silting up now and there would probably be no silting up because the quantity of flood water would still be very considerable. The ordinary volume of the stream would be very materially increased. If I am to take the evidence which was given by Mr. Hawksley that the dry water volume at Tewkesbury or Worcester, one or the other, was about 90,000,000 gallons a day, we should add 30,000,000 gallons a day to that quantity from the reservoir by reason of the compensation that we are proposing to give, which would make it 120,000,000 gallons at that part of the river which would be constantly working upon the bed, and would produce a very considerable and useful effect. Then the effect of the interception, the capturing of floods, as it was called, by our reservoirs, would be this, that when the reservoirs were empty the floods would be captured, but when the reservoirs were full, and they would be full at certain seasons of the year because we can only take two-thirds of the water in average years, then the floods would go down just as they have gone, simply moderated to a limited extent by the area of the reservoirs producing a more regular effect upon the lower reaches of the river. Therefore you would have every year floods as big as they ever were, but you would not have so many of them.

6664. (*Mr. Harrison.*) You would quite expect, you should not, that the question of the effect upon the river would be the great battle-field before any Committee of Parliament?—I believe it would be the only battle-field upon which they could hold their ground; I think it is very likely it might be so.

6665. In the case of the Glasgow Waterworks Bill, did not the officers of the Admiralty report that your abstraction of water from Loch Katrine would affect the navigation of the Firth of Forth?—They reported one year, that the anchorage of St. Margaret's Hope which is 60 feet deep would be destroyed, and they reported nothing against us the second year.

6666. (*Sir J. Thwaites.*) What has been the result upon that anchorage?—Nothing that I am aware of; it is not destroyed certainly, and there has been no injurious effect whatever produced.

6667. (*Chairman.*) What observation have you to make with reference to the danger of large reservoirs, which has been urged as an objection to your scheme?—If the Commission think it is necessary that I should go into that, I should be very glad to do so, but I think you have sufficient evidence upon that point.

6668. (*Sir J. Thwaites.*) I presume with reference to that question, that there is no difficulty with ordinary care in making a dam sufficiently strong to resist the pressure of water of ordinary height?—No, not if the ground is properly selected. Of course there is ground in which it would be almost impossible to make reservoirs, but in the cases of my proposed reservoirs, the sites of some of them are almost absolutely impervious, being unfissured silurian rocks, which are excessively dense, and there is no difficulty whatever in getting perfectly watertight foundations; in other cases, take the Trefeglwys reservoir for instance, the bed of the valley there is all very hard clay, and shale beneath the clay, and shale is always a material that we desire for the foundation of reservoir embankments. The highest embankment is only 80 feet, they vary from 70 to 80 feet, and there are many embankments in this country very much higher than that, and in much more difficult and dangerous positions. In fact one or two embankments which have burst, bear testimony to the safety with which embankments may with ordinary care be constructed. The Bilberry reservoir which burst in 1852 was so badly constructed that the water leaked through the bottom as rapidly as it entered, it never went over the waste weir, and the only occasion, on which it ever rose to the top was the occasion on which it was cut down, and yet it stood in that insecure condition, neglected by the people who ought to have attended to it for a great number of years, after its construction.

6669. (*Chairman.*) The next point of objection to your scheme is the danger of freezing in the aqueduct, what remark have you to make upon that?—I cannot myself apprehend any difficulty about freezing, you have had some evidence given before you with reference to the danger of freezing. It has been stated that the water in this canal would become jelly ice, and that if it travelled at all, it would go glacier fashion, and that it would become glue and would not move, I think all those are rather figures of speech than anything else, and that there is really no serious objection which can be urged against the scheme on that score, The Commission have had some evidence as to the effect of frost upon the New River in 1813–14 and that is the only instance which has been adduced by anybody. In that one year certainly, when a fair was held upon the river Thames, there was an interruption to the flow of water. The quantity of water which would then be taken by the New River Company I have not been able to ascertain, but it would be very much smaller than it is now, it is only a shallow narrow stream, and it would be much more liable to freeze than such a conduit as I propose, which would be 10 feet deep in water, and about from 26 to 30 feet wide. It would be deeper than the river Thames at Kingston, and in its ordinary state the river Thames never becomes jelly ice, it never becomes a glacier in modern times, and it never becomes glue, it has always proceeded to the sea without inundating the

J. F. Bateman, Esq.

11 March 1868.

adjacent country, though its surface has on one or two occasions been covered with ice above old London Bridge. Since old London Bridge has been removed, that does not occur, and no fairs have been held upon the ice since. Then in the case of the Manchester Waterworks which have a great number of open aqueducts, not more than three or four feet deep, and some of them not so deep as that, at elevations of 700 to 1,000 feet above the level of the sea, in a cold exposed country, they never freeze. There is a little interruption now and then by a little floating ice upon the surface which is easily removed. But that amounts to a very small objection indeed, and the only evidence which you have had really before you, with the exception of the instance of 1813-14, is that of the engineer of the New River Company, who states that they have in severe winters a little trouble, and that the cost of breaking the ice is from 500*l.* to 700*l.* in a severe winter. That of course is not every winter, it is merely in a severe winter, and just as much as rivers now flow (for this would be a river of very considerable size) without doing any injury to the adjacent country by refusing to go on, so this river would flow; I cannot conceive the possibility of its being any otherwise.

6670. (*Sir J. Thwaites.*) It might lessen the capacity of discharge, might it not?—The moment it freezes over then, of course, it is a covered conduit, and the friction then is somewhat increased, but the result of that would simply be to raise the surface of the ice until it got a little extra depth, or until the extra sectional area with the reduced velocity balanced the account. When covered by ice it would be exactly like a covered conduit, and there would then be no farther difficulty until the ice broke up. It might require some cost and some labour and some attention to get quit of it then, but that is the only thing. It is very different to a canal inasmuch as a canal is in stagnant pools, but this would be a river constantly flowing, with a speed of a mile and a quarter or a mile and a half an hour.

6671. Have you observed, in long tunnels, what length is necessary to raise the temperature of the water?—I cannot tell you that, but I know this, that in the winter of 1860-61, which was the severest winter that we have any record of—a much severer winter, as far as the record goes, than the winter of 1813-14—the temperature fell in that winter to 12 and 14 degrees below zero—about 44 or 45 degrees of frost,—and we have no record in this country of anything equal to that previously; that was the year after the Loch Katrine waterworks were completed. The works were only completed so as to take the water to Glasgow entirely, early in 1860. I was very anxious about my green masonry, but Loch Katrine never froze: the water was never lower than 39 degrees of temperature, that is to say, 7 degrees above freezing point. There was not a particle of ice upon the whole of the surface of the loch, and in the 26 miles which the water had to travel between Loch Katrine and the Mugdock reservoir, near Glasgow, it gained two degrees of temperature, and it emerged at 41 degrees.

6672. (*Chairman.*) When you speak of the temperature in that year being 45 degrees of frost, of what place are you speaking?—That was in Scotland, and in many parts of England it was the same also.

6673. Was it not colder in England at that particular time than it was in Scotland?—It was generally, but it was not in the neighbourhood of Loch Katrine; in the neighbourhood of Loch Katrine it was 12 degrees below zero. Every part of Scotland being so near the sea the temperature is generally higher than in the interior of England, but in the neighbourhood of Loch Katrine it was 12 degrees below zero.

6674. (*Col. Harness.*) Was 39 degrees the temperature of the bottom of Loch Katrine?—No, that was the surface temperature; we could not tell the temperature of the bottom; it is 800 feet deep.

6675. (*Sir J. Thwaites.*) You do not apprehend any danger, do you, from the mixing of snow with your water in the aqueduct?—Not the slightest; a little trouble and expense occasionally, but danger and difficulty none.

6676. (*Chairman.*) Speaking from your own experience, you have not found any inconvenience in the system that you have now in operation?—That is so. I have never experienced any serious inconvenience. There has been a little trouble in severe winters, but nothing like a serious inconvenience—nothing which could be urged as an objection to my proposed scheme.

6677. (*Sir J. Thwaites.*) The Glasgow aqueduct is under cover all the way, is it not?—Yes, the Glasgow aqueduct is under cover all the way, but in Manchester we have many miles of open watercourse, much smaller, and of course a frost would have more effect upon a small one than upon a large one.

6678. (*Mr. Prestwich.*) Are not the reservoirs at Manchester subject to freezing?—Very little; scarcely ever. I do not think that any of the larger reservoirs in the Manchester waterworks have ever been frozen so as to bear.

6679. The great depth of Loch Katrine has no doubt very materially to do with its freedom from freezing?—Yes, I am speaking of the large reservoirs which vary perhaps 60 to 70 or 80 feet of water, and I do not think they ever freeze sufficiently to bear. I never remember it. Of course the water is kept warm by the great depth, and in the very large bodies of water which I propose the same effect would be produced.

6680. (*Chairman.*) The hardness of the present water is considered by some persons to be unobjectionable, and some persons are of opinion that the present water would be preferable to soft water. Have you any remarks to make upon that point?—You have had before you nearly 50 witnesses, of those 16 had not any occasion to express an opinion upon the quality of the water, and they did not express an opinion, it did not fall within the scope of their evidence. You have had 27 who have all expressed an opinion in favour of soft water, some of them very strongly in favour indeed. You have one single gentleman who has expressed a decided opinion in favour of hard water, and you have had one gentleman who has expressed a qualified opinion in favour of hard water. Amongst those who have expressed a very strong opinion in favour of soft water are Mr. Rawlinson, professor Way, professor Ramsay, Mr. Duncan, Dr. Lyon Playfair,—to whose evidence I must especially draw your attention,—Mr. Simon, Dr. Farr, who also very specially referred to it, Dr. Parkes, and Dr. Frankland, and with him Dr. Odling. I would refer upon that point to the evidence which I gave on the first occasion, on the second day on which I had the honour of being examined before you. I read that evidence over this morning, and I do not think I can add much to the facts which I then stated, nor put them in a better form. I mentioned that in my own house I saved half the quantity of soap which I formerly used, by the introduction of soft water at my house in the country, and that I saved from 4*s.* to 5*s.* a head in a year. I find that the soap which I buy for my household in large quantities cost me, before the introduction of soft water, between 10*l.* and 11*l.* for about 15 months' consumption, that since the introduction of soft water, which I introduced in the autumn of 1864, the soap which I previously used in 15 months now lasts me more than two years, my household consisting almost exactly as nearly as a household can do of the same number of inhabitants, and under the same conditions, in fact if anything there is a larger consumption of soap now going on, or rather, the operations which require soap are now of a more extended character than they were previously to the introduction of soft water. I save 5*l.* a year, and if I measure that by my population by from 20 to 25, I save from 4*s.* 6*d.* to 5*s.* per head per annum in the use of household soap alone. This does not include the soap

which is used in the family bed rooms, not toilet soap, but merely the household soap and the soap used by the servants. I simply add that to the evidence which I have already given.

6681. (*Mr. Prestwich.*) What was the hardness of the water which you previously used?—I have not had it analysed, but it certainly was harder than the London water. I should suppose it would probably be from 20 to 25 degrees of hardness.

6682. Was it water out of beds of gravel, or what?—It was a water out of the lower greensand from a bed of limestone which is just on the level of the river. The Alton branch of the river Wey runs through my property. I get hard water exactly on the level of the river, about 21 feet below the level of the house, and it is, I presume, the lime or chalk in the water of the river which gives the hardness to the water. The soft water is about six-tenths of a degree of hardness. I bring it about a mile; it comes from the lower greensand also, but some distance, 20 or 30 feet above the level of the river.

6683. The water of that district generally is very soft water, is it not?—Generally very soft water. I may observe that if the saving were only 2*s.* a head a year upon the population of 3,000,000 in London, that would be 300,000*l.* a year, the saving of soap alone, to say nothing of the wear and tear of clothes and all other things which might enter into the consideration; and the saving in soap alone would pay the interest of the whole outlay which is supposed to be necessary.

6684. Could you ascertain the hardness of the water which you were using before, and put it in?—I will endeavour to do so. The spring itself, which I now bring to the house, Dr. Frankland is analysing for the purpose of giving some information with respect to it before this Commission, I believe.

6685. (*Chairman.*) The next point is the danger of interference with the conduit, and the interruption of the supply in troublous times, have you anything further to say upon that?—I think I have already gone into that. I may merely observe that I do not see very well how anything could be easily done to intercept the supply to London.

6686. Some doubts have been expressed as to the possibility of bringing water so great a distance as 180 miles from Wales to London; what is your view upon that subject?—It seems to me quite as easy to bring it 180 miles as 18 miles if you have the proper appliances, nor do I now quite understand where the difficulty is supposed to exist. It may be more liable in proportion to its length to be interfered with, but there is hardly anything which can be easily interfered with. Much of it would be in tunnel, and it would be nearly the whole in the solid, because in constructing works of this kind I avoid embankments as far as possible. I put nothing of this kind upon embankment as a matter of practice, and only here and there over a gorge would the aqueduct be susceptible of being injured. Stop-gates and other appliances would be introduced for shutting off the water here and there for the purpose of examination, or for repairs, and there is no repair that I can conceive of which would take more than eight or ten days to execute, and you have service reservoirs holding three or four weeks' supply, and during the time of the repairs the water would be drawn from them exclusively. I cannot myself see any difficulty whatever.

6687. Do you draw any comparison between the mortality of those towns which have a supply of hard water, and those towns which have a supply of soft water?—With your Grace's permission I should like to make a few observations upon the tables put in by Dr. Letheby upon that point. Dr. Letheby gives a number of towns, distinguishing those having water of more than 10 degrees of hardness as hard water supplies, and under 10 degrees of hardness, as soft water supplies. Ten degrees of hardness is a perfectly fanciful distinction, the proper distinction between hard water and soft water is just as clear as the distinction between day and night. The terms "hardness" and "softness" were first reduced to anything like scale by Dr. Clark who introduced the soap test. All water that does not curdle soap is soft water, and all that does curdle soap is hard water. All water containing less than four or five grains of lime or other soap-destroying ingredient will not curdle soap, and therefore that is soft water; all water containing more than five grains will curdle soap, and there begins hard water. Anything above that is purely an arbitrary and fanciful distinction which anybody might put at anything he chose, and therefore that table which Dr. Letheby gives is not a table correctly describing towns with hard water or with soft water at all. Again, many of the places which he adduces are small places in notoriously healthy countries with hardly what you may consider an urban population, almost a rural population, and they are not at all to be compared with a dense population in a city like London.

6688. (*Sir J. Thwaites.*) With regard to the point at which water ought to be declared hard or soft, is it five degrees or what is the point?—About four or five degrees. Just as day fades into night and night fades into morning, so softness and hardness die away, the one into the other. About four or five grains of lime, or other soap destroying ingredient, is just the turning point. You can hardly tell to a degree. We may put it in this way, all under four degrees is certainly soft water, and all above five is certainly hard water, of course varying in hardness as the night varies in darkness. In order to show how utterly impossible it is to draw any conclusion from the mere fact of mortality, I will refer to the cases of Manchester, Salford, and Chorlton, they are all supplied with the self-same water from the same district, and two of them are, perhaps, of precisely the same character. The mortality of the three places combined reckoning upon the standard mortality of the country is from 29 as nearly as possible to 30 per 1,000, reckoning upon the actual population it is 28 per 1,000, and the total population there is 479,000 persons. The city of Manchester only contains 236,000 persons, the mortality upon the standard population of the country is $33\frac{1}{2}$ and upon its own population it is $31\frac{1}{2}$ per 1,000. Chorlton, which is a part of Manchester, and contains 147,000 inhabitants has no greater mortality than $25\frac{2}{3}$rds per 1,000 upon the standard mortality of the whole country, and as nearly as possible 24 upon its own population. So that in the same town you have a variation from 32 to 24, the same water being delivered to both parts of the town, showing that the mortality really gives you no indication of the effects of hard or soft water.

6689. (*Sir B. Phillips.*) Are they all supplied from the same source?—Exactly the same, and yet you have a mortality in one part of the town of 32 per 1,000, and in another part of the same city you have a mortality of 24 per 1,000, the smaller population being that of Chorlton—146,000 persons.

6690. Is not Chorlton less closely populated?—Yes, there is a difference in that respect; there are other causes than the water. No doubt it is attributable to the fact of the population being less dense, as well as to other causes. I will not go further into that, because what I have just mentioned shows that that is not a test to apply as to the effect of hard or soft water upon the health of the population. I should like to add, upon that point, a letter which I had intended to put in before with reference to the water of Dublin, which has recently been introduced into a portion of the city from the new works upon the river Vartry. It is a letter from the principal of the St. Mary's Industrial School, in Stanhope Street, Dublin, and was sent to me by Sir John Grey, M.P. It is in these terms:—"It is with much pleasure "I intrude upon you these few lines, to say what "great satisfaction and comfort we have since the "new supply of water has come into operation. "We consider it a great saving of expense to a "large institution like this, where there is an ex-"tensive laundry. The softness of the water in the

J. Bateman, Esq.

11 March 1868.

"present supply has enabled us to give up the use of "soda, which is necessary in other cases to make the "soap act on the linen. It is not at all required with "the Vartry water, which in its own nature is soft "and mellow. We find a saving of at least a third "of the quantity of soap before used by us for laundry "purposes. We consider the water a great blessing, "and with the city and public at large must feel "grateful to those who have exerted themselves to "procure for us such a boon." It is merely an independent confirmation of my statement that from one-third to one-half the soap, from whatever part of the country the information comes, is the actual saving by the introduction of soft water. The Vartry water is equal pretty much to the Manchester water. It is not perhaps quite as soft as the Loch Katrine, but not far off; and the water for which it has been substituted is the water of the Grand Canal and the Royal Canal, which are about from 18 to 21 degrees of hardness, or rather harder than the London water.

6691. (*Chairman.*) Is that saving in soap from the use of soft water as compared with hard water produced when the water is cold, or after boiling?—There evidently it is after boiling, because it is as to the laundry principally that they speak of it.

6692. We have had it stated in evidence that, given a hard water and a soft water, if you boil both, there is very little difference in the hardness or the softness of the two waters after that process; do you agree with that?—Yes, if you boil the water long enough: but water seldom is boiled long enough. Dr. Frankland, in the evidence which he has given you, shows that ordinary boiling scarcely reduces the hardness; he takes the water in his own house and in the Athenæum Club, and he says that the water which he draws the first thing in the morning, having been under heat all night, is many degrees softer than the cold water, but that after that water has been drawn off during the remainder of the day, there is very little difference between cold water and the hot water.

6693. (*Mr. Prestwich.*) Reverting to the more important consideration of the effect of water upon health, which you have just touched upon, what you have observed with regard to different portions of Manchester would be applicable to all large towns; that is to say, Liverpool, or Sheffield, or any other large town would show the same differences of effect taking different portions of the town, but taking it in the aggregate, can you show any different result arising from the use of soft water as compared with hard water in any towns which have been supplied with soft water?—It is very difficult to do that. My own firm conviction is that soft water is very much more wholesome than hard water, but I do not think that the use of hard water leads to fatal diseases, and on that account probably the effects of water have not been observed by medical practitioners. But I am quite sure that anybody who is affected with particular disease, calculus, for instance, will speak as to the beneficial effect of soft water as compared with hard water; otherwise I do not know that there is much to prove it, but certainly soft water is wholesome.

6694. Have you any returns from any towns in which soft water has been introduced to show the difference in the health of the population?—In Whitehaven, which was supplied with hard water and very badly supplied, a fresh supply was introduced some 20 years ago. The mortality at Whitehaven, on the average of the four years previously to the introduction of the Ennerdale Lake water, which is a very soft water, was about 35 or 36 per 1,000. In the four years succeeding the introduction of that water it fell to an average of 23 or 24 per 1,000, and the fourth year it was only 19 per 1,000.

6695. Has there not been a further alteration in the mortality since that period?—I have been told that the mortality has increased in Whitehaven since then, but for four years previously to the introduction of soft water, and for four years subsequently, that was the state of things. I had occasion to investigate it at that time because we were then fighting the question of soft water for Glasgow, but what the mortality is now I do not know. In that particular case the introduction of water of any kind might possibly have produced the same effect, but it was soft water, and the mortality was reduced; there was no other cause apparently to account for the difference, and upon the introduction of soft water this remarkable fall in the mortality occurred.

6696. Was the supply in any way defective in quantity before that?—Yes, it was, certainly.

6697. (*Sir J. Thwaites.*) Is it not difficult to determine the question as to the effect of hard and soft water upon the health, so many other causes being in operation; for example, in the case of the small town to which you have referred there might have been many deleterious substances in the water which might have affected the health of the inhabitants apart from the hardness of the water?—No doubt.

6698. Then there are sanitary arrangements frequently accompanying a fresh supply of water which would have a tendency to improve the public health?—Yes, no doubt. In the city of Manchester, a good while ago Dr. Percival resided who was a very eminent physician in his day, and he wrote upon the Manchester water which was then obtained from the new red sandstone and contained several earthy salts, and he especially attributed many of the complaints to the water which was then used, and he mentions what they were. Now those complaints to a great extent have ceased, they are not now common complaints in the city as they were in his time, and the same negative evidence if it can be considered negative evidence, occurs at Paisley where hard water previously existed and soft water was afterwards introduced, and where from the evidence of those who know the circumstances complaints of stone in the bladder which were common before ceased.

6699. (*Mr. Prestwich.*) I presume the water from the new red sandstone contained sulphate of lime?—Yes, what he calls selenite. I do not know what he means by selenite, but he said it contained selenite to a great extent. One argument which I have heard very stubbornly used in favour of hard water is that it is absolutely essential to the formation of bone, but the finest and most muscular men, and men of the most bony development that we have are men who live in soft water districts, and cannot get hard water, and those who live in districts where they get nothing but hard water are certainly the smallest men, and of the smallest physical development that we have in Great Britain.

6700. The oatmeal they use in the north contains sufficient carbonate of lime to render them independent of it in the water?—I suppose they have other things to live upon; but what I mean is, that they do not depend for their bones upon the water they drink.

6701. (*Chairman.*) With regard to the area from which water could be obtained, are we to understand that you think that the area could be increased if it was found necessary?—Yes. I gave some evidence upon this point before. It was alleged that it was impossible to get an additional area; but I have upon the map which is before the Commission shown the additional area which may be obtained. It is approximately correct; it shows the area which may be added to the area which I have already included. First of all there is the piece which is striped with green, which is the River Severn proper. That is a district which I omitted in the first instance; because at the time the investigation was first made, there were certain lead-workings upon it which I was anxious to avoid; but when Mr. Pole was over the ground he found that those lead-workings had ceased, and that that water was as good and as fine and pure as any other water in that district. That area contains 12,301 acres, and that would give 2,225,000 gallons per 1,000 acres; that, therefore, would give 18,000,000 or 20,000,000 gallons a day more for the supply of London, after giving compensation. Then there is

that part to the north of the pink which is coloured yellow; all that is a district which may be brought into the supply; and the part which is coloured yellow to the east of the Trefeglwys reservoir; both those districts being in the Severn Valley may also be added to the drainage ground; and those parts which are coloured dark orange, lying to the south of the green part, are in the valley of the River Wye, and they may all be brought into the Trefeglwys reservoir, or to other suitable situations, for conveyance to London. Altogether those additional pieces contain 117,399 acres, and they would supply to London, if the water were stored, upwards of 200,000,000 gallons a day, after compensation was given. The following table will give the additional acreage which may be obtained:—

Welsh Scheme.

Memorandum of Area of additional Drainage Ground, contiguous to the proposed Scheme, which would be available at a future time for extending the supply.

	Area in acres.
Main branch of the river Severn, omitted from present scheme on account of lead mines, which were understood at the time the scheme was laid out, to pollute the stream. Mr. Polé finds that the mines are insignificant, and that the stream is consequently available for purposes of supply - - - - - - -	12,381
Afon Marteg Valley, to the south of the Dulas and Twlch streams. In this valley a reservoir has been surveyed of a capacity more than sufficient to utilize the water of the district -	4,450
The river Wye, above Llangurig and the stream flowing from the hills to the south of that place, 27,270 + 5,679 acres - - - - -	33,949
The hills and streams lying to the west of the Dulas and Twlch valleys, and to the south of the Llanidloes - - - - - -	16,665
The district to the north-east of the river Vyrnwy, 41,113 + 8,841 - - - - -	49,954
	117,399

All this additional drainage ground lies on the east of the mountain ranges of Plynlimmon and Aran Mowddy. Considerable drainage ground could also be obtained on the west side of the hills, taking the upper portions of the Dyfi and other streams now flowing into Cardigan Bay.

6702. (*Sir J. Thwaites.*) That gathering ground which you have now referred to, colored orange, is not so good as the upper part, that is to say, it is not so free from agricultural operations?—The upper portion of it, on the flanks of Plinlimmon, is quite as free. There is no doubt a little difference, but the Severn goes quite up to the slopes of Plinlimmon, and this brown part on the map goes up to the very summit, and all that district is quite free as from objection as any other part (*describing the same*). Some of the parts are certainly more or less cultivated, That is altogether exclusive of anything which may be obtained from the western slopes of those ridges if it should be considered desirable to go further, but you have in that district upon those coloured patches, 500,000,000 gallons a day for London and the district, and I should think that is sufficient to contemplate for a long time to come.

6703. (*Chairman.*) Have you any further remarks to make upon Messrs. Hemans and Hassard's scheme?—I beg leave to hand in an estimate of the cost of obtaining water from Cumberland on the same scale of prices, and for the same class of works as my own estimate is based upon, because it is impossible to compare the cost of two different works, except the works are laid out in the same manner, and the same prices are applied to them. I have not a word to say against the Cumberland district as being a proper district for supplying water; the water is abundant and good, the drainage ground is good, and I have no objection whatever to make to it, but it lies at too great a distance from London to be available to London as compared with districts which are nearer. I know the lake district well. I have lived in it, and made reservoirs and waterworks in it, and I know all the circumstances, and there is nothing about the scheme which I have any occasion to complain of, but the cost of collecting water and storing it is quite as great as the cost of the collecting and storing water in the Welsh district, although they have the advantage of starting with natural lakes and in Wales we have to make them artificially. My estimate of the cost of constructing the reservoirs which I have laid out and collecting all the water, upon very carefully considered plans, is 1,060,000*l.* That includes all the flood-water courses and the reservoirs and all means of collecting and storing. The cost of storing and collecting water in the Ulleswater scheme of Messrs. Hemans and Hassard according to their own estimate is 1,013,000*l.*, being only 46,000*l.* less than my estimate for the Welsh district. I adopt their estimate, I will not find any fault with it, but I may observe that my own estimate for the works which are required in that district would have come to more than that, it would have been some 200,000*l.* more than the cost of collecting in the Welsh district. Therefore although they start with natural lakes, yet the other disadvantages of making very large flood-water courses and tunnels for the purpose of conducting water from one valley to another, and the cost of making embankments at Haweswater, Thirlmere, and other places balances any other advantage, and it makes the cost as great in treating their district as the cost would be in treating the Welsh district. But then comes the very important difference of distance. From my reservoirs in Wales to the service reservoirs near Stanmore it is only 171 miles in the one case and 173½ miles in the other. Messrs. Hemans and Hassard have fixed upon the same place for their service reservoirs as I have myself with a difference with respect to level for their service reservoirs, but the distance which they have to bring the water is 270 miles. They have further than that the disadvantage of having only about the same amount of elevation to start with which I start with. I think they start, if I remember rightly, at something like 465 feet. I start at 450 feet, but they have a greater distance to perform their journey in, so that I am enabled to give to my covered aqueducts 14 inches fall in a mile, while they can only give 6 inches. I give 6 inches of fall a mile to my open aqueduct, while they can only give 4 inches, and I give 5 feet fall in a mile for the syphon pipes, while they only allow 20 inches. The consequence of that is that their works must necessarily be on a larger scale to convey the same quantity of water. To get over the difficulty of fall they have proposed to make wrought-iron tubes of 8 feet in diameter for crossing those parts of the country in which they require to use pipes. They cannot make an open or covered aqueduct of the ordinary construction, and by the adoption of that system they not only do with a fall of 20 inches, as compared with 5 feet in a mile, but they save about three millions of money, as compared with the cost of introducing cast-iron pipes. Then comes the question of whether wrought-iron pipes or tubes are suitable for the conveyance of water. Wrought iron oxidises very rapidly in soft water. You cannot protect wrought iron as you can cast iron in the way I showed you with a pipe the other day. I have tried it over and over again, but the hard epidermis of wrought-iron which is all rolled, is such that you cannot burn the asphalte coating into it as you can into cast iron, which is to a certain extent porous and would absorb a certain portion of the asphalte at the proper temperature when it is immersed in it. I have tried it over and over again, because I have been very often anxious to use wrought-iron, but the consequence is that everything of that kind which you put upon wrought iron scales off. In order to obviate the difficulty of corrosion, Mr. Hemans and Mr. Hassard proposed to line the pipe throughout with a certain thickness—about half an inch in thickness. I think—of Portland cement, but that will scale off, I have not a doubt, in

J. F. Bateman, Esq.

1 March 1868.

the same way as any other coating will scale off, because the scaling takes place in consequence of the rust which occurs upon the surface of the iron, and in coating cast-iron pipes, if we allow rust at all to exist before the pipes are coated the coating all comes off; the rust goes on beneath the coating and throws it off, You cannot put on a Portland cement lining without wetting it, and at the same time you wet the iron, and corrosion will take place. You cannot make a coating simply of half an inch of Portland cement so water tight that under no pressure shall it be impervious to water, and under 200 or 300 feet of pressure, which it would be liable to, the water would penetrate down to the iron and corrosion would take place, and upon the corrosion taking place the Portland cement lining would fall off and would expose the iron to the active corroding operation of the soft water. However, giving them the advantage of the wrought-iron tubes, but putting everything else upon the same scale of prices, taking the same class of work and the same scale of prices as those which I have adopted in the estimate for my own scheme, the difference is this. From Wales, for 230,000,000 gallons a day, my total estimated cost is 10,317,205*l.*, being at the rate of 44,823*l.* per 1,000,000 gallons. Messrs. Hemans and Hassard's own estimate for 250,000,000 gallons is 11,679,260*l.*, being at the rate of 46,717*l.* per 1,000,000 gallons; that is their own estimate upon such a class of work as they have adopted. If it is estimated according to the class of work which I have adopted and the scale of prices which I have allowed, but adopting their 8 feet tubes, the estimate for their works comes to 18,929,914*l.* for 250,000,000 gallons, being at the rate of 75,720*l.* per 1,000,000 gallons; and if cast-iron pipes were to be used instead of wrought-iron tubes, the estimate of the Cumberland scheme would be, 21,988,664*l.*, or, per 1,000,000 gallons, 87,954*l.* I will not say another word upon their scheme in any way. There are difficulties with reference to getting over some parts of the country which are very great indeed. I will not refer to them, but, simply putting both estimates upon the same footing, their estimate must of course be more, in consequence of the greater distance and the larger scale of work which they must adopt. I will here beg leave to hand in the following table:—

TABLE showing comparative Cost of obtaining a daily Supply of 230,000,000 Gallons from North Wales, and 250,000,000 Gallons from the Cumberland Lakes.

——	Gallons daily.	Total estimated Cost.	Cost per Million Gallons.	Distance to Stanmore.	Fall per Mile.		
					Covered Aqueduct.	Open Aqueduct.	Syphons.
		£	£	Miles.	Inches.	Inches.	Ft. ins.
From Wales - - - -	230,000,000	10,317,205	44,823	171 or 173½	14	6	5 0
From the Cumberland Lakes according to Messrs. Heman's and Hassard's estimates - -	250,000,000	11,679,260	46,717	270	6	4	1 8
From the Cumberland Lakes according to class of work and scale of prices adopted by Mr. Bateman—if wrought-iron tubes, 8 feet diameter, be adopted - -	250,000,000	18,929,914	75,720	270	6	4	1 8
From the Cumberland Lakes according to Mr. Bateman's estimate,—if 4 feet cast-iron pipes be used instead of 8 feet wrought-iron tubes, as proposed - -	250,000,000	21,988,664	87,954	270	6	4	1 8

6704. (*Sir B. Phillips.*) You say that to bring 250,000,000 gallons of water from Cumberland according to their prices will cost 11,679,000*l.*?—Yes.

6705. If the works are carried out in the same way that you propose to carry out yours, they will cost 19,000,000*l.*?—Yes, that is so.

6706. Wherein lies the difference in the construction of the works?—In the greater distance, they have one hundred miles greater distance to bring the water.

6707. But their estimate with which you do not agree, is 11,679,000*l.*, that is to say, supposing they carry out the works as they propose to do?—That is their estimate. If the estimate is made exactly upon the same scale, and upon the same prices, and the same class of works that my estimate is based upon, which is the only way in which you can compare the two, then it would cost about 19,000,000*l.*

6708. (*Sir J. Thwaites.*) You do not differ do you as to the sustaining power of the culvert?—They have to increase the dimensions of their culvert in order to compensate for the greater fall.

6709. But you do not differ from them in calculating the capacity of the tunnel at the given fall which is 6 inches per mile?—I do not find any fault with that. There is one great work which they have at the commencement; they have to pass under Kirkstone Pass, which is one of the highest passes in England, some 1,200 or 1,300 feet below the level of the summit, and there is a mile and three-quarters which they propose to tunnel without shafts, adopting the system of working which has been adopted in the Mont Cénis tunnel. I do not of course mean to say that that could not be adopted.

6710. They have taken all that I presume into consideration in their calculation. It appears such a monstrous difference between the two estimates that they should estimate their work at 11,679,000*l.*, and that your estimate for the same work over the same ground is 19,000,000*l.*?—It is not the same work.

6711. (*Mr. Harrison.*) You have got a given fall per mile which is greater than theirs, therefore your general works are less in extent than theirs?—Yes, I require a conduit of smaller dimensions.

6712. On the other hand they have taken a very much less fall per mile, and they require a much larger section; but they say that in consequence of the diminished velocity they are able to make it with a less amount of protection in masonry work; assuming that to be so, does not it amount to this, that supposing it were put into the hands of either yourself or Mr. Hemans to do, and supposing it were desirable to apply their section and their description of works to yours, it would be quite applicable?—Yes, just the same.

6713. Whereas in the case of the Cumberland scheme they could not apply your sections and your mode of doing the work to theirs?—They could not. And if my fall were considered to be too much, which it certainly is not, I could reduce the fall by stop-gates here and there, and so make the fall exactly the same as theirs. But their works also are of a very much heavier description, and they have in addition to a much greater length a very much greater proportionate length of syphon work, which is a very expensive portion of the work, than I have. And there is one point which I must also mention, in contrasting one scheme with the other. Here is every detail of the cost of their work upon my own scale of prices exactly; I have worked them out myself. Those prices are on the same basis, and if the one is handed in it is right that the other should be handed in.

CUMBERLAND LAKES SCHEME.

SUMMARY of Estimate of Cost calculated on same Character of Work and same Prices as in Mr. Bateman's Estimate for the Welsh Scheme.

Reservoirs, lakes, and works of storage and collection		£1,013,000
Messrs. Hemans and Hassard's estimate is adopted.		
Aqueduct from Ullswater to Edgware:		
1st section from Ullswater to Ambleside (for particulars see below) 8 miles	£734,668	
2nd section from Ambleside to river Tame at Stockport (for particulars see below) 102 miles	7,040,625	
3rd section from river Tame, at Stockport, to Edgware (for particulars see below) 160 miles	7,962,500	
		15,737,793
		£16,750,793
The above estimate is on the assumption that 8ft. wrought-iron tubes are adopted. If 4ft. pipes were used, the extra cost would be 3,058,750*l.* (for particulars see below), or the total cost of the aqueduct from Ullswater to Edgware would be (15,737,793*l.* + 3,058,750*l.*)		18,796,543*l.*
Service reservoirs at Edgware and works for distributing water to existing centres of supply. This is assumed at the same estimated cost as for the Welsh scheme; but the lower level at which the Cumberland aqueduct is proposed to terminate will necessitate a larger outlay in the piping in consequence of the diminished head		2,179,121
Total		£18,929,914
If 4ft. pipes be used the total cost would be		£21,988,664

ESTIMATE of AQUEDUCT from ULLSWATER to LONDON

1st section from Ullswater to Ambleside, distance 8 miles, 2 miles open cutting, 6 miles tunnel (see Mr. Hassard's evidence, question 733).		
Open watercourse from lake to commencement of tunnel, 2 miles,—cutting 20 feet above conduit at the lake, and 50 feet at tunnel entrance, or 12 yards deep on the average.		
Excavation—at lake 90 cubic yards, per yard lineal, at tunnel entrance 400 cubic yards, per yard lineal, average 245 cubic yards at 1*s.* 6*d.* per cubic yard, including contending with water from river, &c.	£18 7 6	
Brickwork or stonework, 5⅔ cubic yards, 20*s.*	5 13 4	
Ashlar coping, 14½ cubic feet, 2*s.*	1 9 0	
Concrete, 4½ cubic yards, 10*s.*	2 5 0	
	£27 14 10	
Sundries	0 15 2	
Per lineal yard	£28 10 0	
1,760 lineal yards at 28*l.* 10 0,	£50,160 per mile.	
Bridges, drains, fencings, &c.	3,000	
	£53,160 per mile.	
2 miles at 53,160*l.* per mile		£106,320

CUMBERLAND LAKES SCHEME.

PARTICULARS and estimate of proposed 8 feet wrought-iron tubes for syphons.

8 ft. tube with fall of 20 in. per mile will discharge about 82,000,000 gallons in 24 hours.

Area, 50·2656 s. ft., velocity 2·41 ft. per second.

Theoretical discharge		65,173,320 gallons per day.
Add 25 per cent. for difference between actual and theoretical discharge	16,293,330	„ „
	81,466,650	gallons per day.

Three lines of 8 feet tubes will be required to deliver 250,000,000 gallons in 24 hours, and average head of water on pipes assumed at 200 feet.

Estimate per lineal yard.

Wrought iron, 9/16 in. thick, weight per lineal yard, 2,966 lbs., say 23¾ cwt. at 18*l.* per ton	£21 7 6
Pipe trench, excavation for three lines, 60 cubic yards in a yard forward, or 20 cubic yards for each line at 1*s.* 6*d.* per cubic yard	1 10 0
	£22 17 6

1,760 lineal yards at 22*l.* 17*s.* 6*d.*
= £40,260 per mile for each tube.

5 per cent. for contingencies	2,013	„	„ „
Land	400	„	„ „
	£42,673	per mile for each tube.	

Say 42,500*l.* per mile.

3 lines at 42,500*l.* per mile £127,500 per mile.

Length of syphons:

From Ambleside to river Tame, at Stockport	32¾ miles.
From river Tame, at Stockport, to service reservoirs at Edgware	15 „
Total	47¾ miles.

J. F. Bateman, Esq.

11 March 1868.

CUMBERLAND LAKES SCHEME.

PARTICULARS and estimate of syphons, if 4 feet pipes adopted, as proposed by Mr. Bateman for his Welsh scheme.

4 ft. pipes, with fall of 20 ins. per mile, will discharge about 15,000,000 gallons in 24 hours.

Area, 12·5664 s. ft. Velocity, 1·74 ft. per second.

Theoretical discharge - -	11,763,658	gallons per day.
Add 25 per cent. for difference between actual and theoretical discharge - -	2,940,915	„ „
	14,704,573	gallons per day.

17 lines of 4 feet pipes will be required to convey 250,000,000 gallons daily, and average head of water assumed at 200 feet.

	Estimate per lineal yard.
4 feet pipe, 1⅜ in. thick, weight per lineal yard, 20 cwt., at 6*s.* per cwt. - -	£6 0 0
Laying and pointing, including excavating and refilling trench - - - -	0 15 0
	£6 15 0

1,760 lineal yards, at 6*l.* 15*s.* 0*d.* = 11,880*l.* per mile for each line of pipes.

Contingencies 5 per cent. - -	598	„ „ „
Total - -	£12,580	per mile for each line of pipes.

say 12,500*l.* per mile × 17 lines = 212,500*l.* per mile.

Length of syphons, 47¾ miles, at 212,500*l.* -£9,146,875

Cost of syphons, if 8 ft. wrought-iron tubes be adopted, 47¾ miles at 127,500*l.* - - - 6,088,125

Additional cost if 4 ft. pipes be used in place of 8 ft. wrought-iron tubes - - - -£3,058,750

6714. (*Sir B. Phillips.*) Your estimate for the Cumberland scheme to bring 250,000,000 gallons of water is in round figures 19,000,000*l.* ?—Yes.

6715. Messrs. Hemans and Hassard's estimate over the same ground for the same quantity of water is 11,670,000*l.* ?—Yes.

6716. In round figures there is a difference of 7,000,000*l.* as between the two ?—Yes.

6717. Do you suppose that the estimates of those gentlemen are insufficient to carry out the works efficiently ?—I have not gone into them, but I do not believe they are sufficient. As I say, I have not gone into them, but I have put both works upon the same basis, and if they can execute their works efficiently for 12,000,000*l.* I can execute the works from Wales for a much less sum than that which I have estimated my works will cost. No doubt the works could be made properly and satisfactorily if they were constructed upon a less expensive scale than that which I have proposed to introduce, but I do not think that any other mode than that which I have adopted should be adopted in dealing with a work of so much importance, which is to last for ever. If it had been my object to have said anything in favour of my own scheme I should have adopted a cheaper work and a lighter estimate, because I could have shown that in three or four years it would have been cheaper to have got water from Wales than to have pumped it from the Thames; but I have stated as clearly as I possibly could that I cannot consider that that is the mode in which the works ought to be executed.

6718. There is always a remarkable difference in the estimates for works of different descriptions; but this large difference between such eminent engineers as you are does appear to be something very unusual, because the one says that it will take 12,000,000*l.* to carry out certain works, and the other says, that in order to carry out the work efficiently in the way in which it ought to be done, it will take 19,000,000*l.*—I say that my estimate is based upon a certain class of work, and I think that that is the right class of work, and if the other is to be worked out on the same scale and the same class of work I estimate that it will cost 19,000,000*l.*

6719. (*Chairman.*) Supposing it be thought right to bring the water from Cumberland and not from Wales, you say that it ought to be brought in the same manner as you propose to bring it from Wales ?—Yes.

6720. And if it is brought from Cumberland in the same manner as you propose to bring it from Wales, it will cost 19,000,000*l.* instead of 12,000,000*l.* ?—Yes.

6721. But you do not mean to say that it cannot be brought from Cumberland in the manner which Mr. Hemans proposes for the prices which Mr. Hemans suggests ?—I have not said so; but if I were pressed I should say that his estimate was too low. I do not find fault with his estimate; I merely say that according to the determination of the strength of the pipes which would be required to bear the pressure that they must be subject to, and taking everything else at the same scale as I have applied to my own works, I estimate them at exactly the same prices.

6722. (*Sir J. Thwaites.*) Are we to understand you to state this, that without going into Mr. Hemans' estimate you have instituted a fair comparison because you have applied your own estimate to the works which are necessary for the purpose in your judgment to bring the water from the other district ?—That is what I have done. You cannot compare two things together until you get them put upon the same basis.

6723. (*Col. Harness.*) Does not the velocity differ in the two schemes ?—Yes.

6724. Would not that of itself involve a difference in the works ?—No, I think not, because the velocity is very small. The velocity in neither case is such as would be inconsistent with a simple clay bottom.

6725. What is your velocity ?—I think about a mile and a quarter or a mile and a half per hour, or between two and three feet per second. This is what the work must be and what they must do upon the same footing (*producing a section and explaining the same*). The velocity in my own case for conveying 230,000,000 gallons in the open aqueduct is 2·16 feet per second mean velocity. Their mean velocity for conveying 250,000,000 gallons is 1·82 feet per second, being 45 per cent. of difference.

6726. (*Sir J. Thwaites.*) Messrs. Hemans and Hassard have checked their velocity by dams, have they not ?—No, they have not, nor have they any occasion to do so. Of course stop-gates will have to be introduced here and there for the purpose of regulating the quantity of water which would be going down, but there would be no occasion if you were always discharging the same quantity to do that as far as mere velocity is concerned. A river runs on unchecked with a certain degree of velocity, and so this would run on with a certain degree of declivity as it does in Glasgow and Manchester, but of course dams would be introduced for the purpose of regulating the quantity.

6727. It might have an effect upon the cost of construction if you lessened the velocity, because you would construct your works with less solidity than you would if your velocity were increased ?—I was about to say that both these velocities are consistent with the open aqueduct being formed exactly as a simple canal with a clay bottom. It would not disturb a clay bottom, and it would not affect at all a gravel bottom. But then I do not think that that is a proper way to convey water for the supply of a city. You ought to have it lined through. I have adopted in my work because it was most expensive (and I did not want to do anything which might be construed to be in favour of myself) a lining of concrete with a facing of bricks, and I have put Mr Hemans' work upon the same footing. But where you go through a stone country you would adopt the stone of the country, and do it as cheaply as you could. There is not much difference between one country and another, in that respect, in proportion to their length; but in any case I think it should be lined through in such a way as that you can stop off a portion and cleanse it from all corrupt vegetable or other deposit, or for the purposes of any repair that you might wish to do from time

to time. This would be a work for all time in one case as in the other, and it ought to be as perfect as the sewers in London.

6728. They propose to line this, do they not, with native stone?—Yes. I should do so where I pass through a country in which stone would be yielded. They must be precisely the same in proportion to the length of the conduit. I have perhaps a larger district in which I can get native stone than they have, but there is nothing in that which can affect the comparative estimate.

6729. How do you account for the great difference of price?—That is all in detail in my tables. In the first place there is 100 miles difference, which in round numbers is 37,000*l.* or 38,000*l.* a mile, or 4,000,000*l.* sterling.

6730. Then structurally there would be about 3,000,000*l.* difference?—Yes; I have put stronger pipes than they have done.

6731. First of all they have 100 miles greater distance at so many thousand pounds per mile, which will give 4,000,000*l.*?—Yes, that alone would do it.

6732. And you have to make up the 7,000,000*l.*?—Yes.

6733. Then you have structurally to account for the 3,000,000*l.*?—Yes.

6734. Is that due to the substitution of wrought iron in their case?—To a considerable extent that is so, and also to the larger size of the aqueduct, and therefore it would be more costly. The Commission will see at once that this is the size of their covered aqueduct (*producing a section*), and this is the size of my covered aqueduct (*producing another section*). I have taken the same strength and dimensions for the large one as I have for the small one. If that is strong enough for them it is too strong for me, but if it is not strong enough for them, they ought to have added a little to it.

6735. I presume this would have to be varied according to the ground through which you were passing?—Yes, more or less. If you look at the other sections you will see that the aqueducts look very much larger and more costly than this, and the tunnels also must be in the same way. You will observe also that they have only 20 inches of fall for their syphon pipes, whereas in mine I have 5 feet of fall. All these things cause very great differences in the cost of construction. There is one other point which I cannot avoid mentioning, and that is the level at which they terminate near London. The level at which I propose to terminate, which is 270 feet above the Ordnance datum, enables me to construct those great reservoirs, which I had the honour of describing to the Commission the last time I was examined, in such a way, that I have a pressure head to carry the water to every one of the existing high-service reservoirs of the present companies, except those at two or three very high points. In consequence of their greater length, they terminate at such a level that they cannot for instance supply the Maiden Lane reservoir of the New River Company. Instead of having the amount of fall which I have, 5 or 6 or 8 or 9 feet in the mile, to some of these reservoirs, they have to come down to about 2 feet of fall in a mile, 232 feet being the level at which their aqueduct terminates.

6736. (*Mr. Harrison.*) Will you give the level of the discharge pipe from the reservoirs in both cases?—270 feet is the level at which I terminate. I have taken for the conduit to the Maiden Lane reservoir to supply the East end of London, a starting point of 250 feet, which is 20 feet below the level of the service reservoir. I have taken as a starting point for other parts in other districts, 262 feet 6 inches. I might have taken it at the top of the service reservoirs, because those would always be filled, but I have thrown away 7 feet 6 inches, and taken 262 feet 6 inches as a starting point at present to all those other points, and my calculations are based upon that. Messrs. Hemans and Hassard terminate at 232 feet, but then giving them the full advantage of the reservoir being always full, and taking the pressure from the full reservoir, they have 30 feet less than the pressure which I have taken. That has two effects; in the first place it is so low that they cannot avail themselves of the natural features of the country. At the foot of those hills there is a hollow and then the ground swells into breasts of hills, which are closed by embankments across the valley, at the level which I have adopted. They get 30 feet below that, and they get beyond those breasts into the open country where they cannot make their reservoirs so cheaply or so advantageously as the reservoirs which I have selected. Then they are at so low a level, that they cannot supply the Maiden Lane reservoir, and they can only get to the Kent district, if I remember rightly, with a fall of 2 feet per mile, whereas we get there with a fall of about 5 feet per mile, consequently they must have larger pipes. With a fall of 2 feet per mile, a 3 feet pipe will discharge perhaps about 5,000,000 gallons, whereas with a 5 feet fall per mile it will discharge nearly 10,000,000 gallons in 24 hours, so that you have to put two 3 feet pipes with a fall of 2 feet instead of one 3 feet pipe with a fall of 5 feet per mile in order to give the same quantity of water. So that there again is a great increase in the cost of the work, and at the same time you cannot give so high a pressure by 30 feet as you can by terminating at the level which I have adopted.

6737. (*Chairman.*) Will you now proceed to the next point to which you wish to call the attention of the Commission, which is the insufficiency of the supply of the water of the Thames in dry weather at Henley?—That is with regard to a scheme which has been proposed for bringing water from Medmenham to London. It is proposed by that project to bring 200,000,000 gallons a day, and there was evidence given by the gentleman who proposed that scheme as to the quantity of water which the river yielded. In his evidence upon the Metropolis Water Bills in 1851, Mr. Hawkesley described a scheme which he had for supplying London, and he mentioned this:—"At the latter end of the month of June last" (that is, in 1851,) "a short time before the termination "of the severe drought which had so long prevailed, "I measured the water flowing down the Thames "at Bray Lock, and I then ascertained that the "minimum discharge amounted to 200,000,000 "gallons per diem." Now, Bray Lock is 12 or 13 miles below the spot at which it was proposed to take the water at Medmenham; therefore, you could not get 200,000,000 gallons if this measurement be right, and this measurement agrees very nearly with my own measurement and with the evidence which has been given as to the quantity of water in the Thames at Hampton and Kingston. According to Mr. Hawksley's measurement in June 1851, the whole volume 12 miles below this point was but 200,000,000 gallons in dry weather at the end of the drought; and that corresponds with the measurements which have been given in evidence before the Commission with regard to lower points. Therefore, unless you left the whole bed of the Thames dry, which is not a thing to be done, that quantity of water could not be obtained. The fall proposed there is only 1 inch per mile, which gives a very slow velocity indeed for the purpose of delivering 200,000,000 gallons per day. Of course that amount of fall involves a very large area of conduit; indeed, it requires a conduit 40 feet wide and $12\frac{3}{4}$ feet deep, in order to carry 200,000,000 gallons a day; and it requires two covered channels 22 feet wide and 14 feet deep, in order to convey the water. I have taken that in the same way as in the other case, at the same scale of prices, and the same class of work as I have adopted in my own case.

6738. (*Sir J. Thwaites.*) What would the velocity be?—One foot per second. There is a portion of the work which I cannot very easily understand; that is canalizing the river above the point of diversion. I have only put down 100,000*l.* for the aqueduct over the river Thames at Maidenhead, and the whole of the works for canalizing the river above, which I do not

J. F. Bateman, Esq.

11 March 1868.

quite understand; but if it is at all equivalent to what is described it will cost a great deal more than 100,000*l.*, but putting it at that, the whole work comes to 1,932,000*l.*, and the water is brought in then only at the elevation of the Regent's Canal, about 100 feet above Ordnance datum. It then has to be lifted, and the cost attending that, with interest on the outlay, would be quite as much as that for lifting the water from the Thames, as the companies do now, and there is therefore no advantage and no saving at all, even if the water of the Thames at that place were sufficient for the purpose of abstraction. I have not thought it necessary to go into the analysis of any other schemes. Those are the more marked and more promising schemes which in my opinion have been brought before the Commission, and although there are many others I hardly think it is necessary to refer to them.

There is but one other point that I am desirous of laying before the Commission, and that is as to the financial result of the scheme which I have had the honour of describing. The pamphlet which is in your hands was written 2½ years ago, and everything has been increasing in point of population and demand for water since then. The rateable value of property within the metropolitan district in 1867 was upwards of 16,000,000*l.* per annum; 1*d.* in the pound upon that is equal to 67,000*l.* The probable assessable value by the time the works could be completed, say 1875, may be safely taken at 20,000,000*l.* sterling. Of this say 13,000,000*l.* will represent house property. The 20,000,000*l.* of course includes all property. If we assume a domestic rate of 10*d.* in the pound upon all the house property and 2*d.* in the pound upon all property for the public advantage to be derived from a work of this kind, the result would be as follows: 13,000,000*l.* per annum at 10*d.* in the pound would be 541,667*l.*, and 20,000,000*l.* at 2*d.* in the pound for the public rate would be 166,666*l.*, making a total from compulsory rates of 708,333*l.*, and then comes in addition the sale of water for trade purposes. When I wrote that pamphlet in 1865, although I believed from the knowledge which I had of other places that I had not overstated the amount which would be derived from those sources, which I stated at 250,000*l.*, I was under some apprehension that other people would think that I had materially overstated it, as it seemed so large a sum. In the evidence given before the committee on the East London Water Bill of last session all the companies gave the amount of water which had been sold in the year before for trade purposes and their various charges, and the total quantity of water sold for such purposes amounted in round numbers to 5,600,000,000 gallons. Their charges vary from 6*d.* to 9*d.* per 1,000 gallons, with 25 per cent. added for high service. Now, high service means in all cases except one the delivering of water at 10 feet above the ground floor of the house. High service in the New River case means 60 feet above Trinity high-water mark, and a very large proportion of the New River will be that, but in almost every case the water will be delivered by the other companies at more than 10 feet above the ground floor of the house so that to the ordinary charge 25 per cent. would have to be added. Now those are all charges by Act of Parliament from 6*d.* to 9*d.* per 1,000 gallons, with 25 per cent. added for high service. If I were to take it at 9*d.* per 1,000 gallons, which would be probably below the truth, it would come to 210,000*l.* a year upon the water which is now sold, and if you take it at 8*d.* per 1,000 gallons it is 186,660*l.* a year. But they charge a great deal more than either 8*d.* or 9*d.* I have here a report of the proceedings of the vestry of the parish of St. John, Hampstead, for 1867, and amongst other things it shows the price per 1,000 gallons at which the water was supplied, and the quantity in gallons, by the New River Company and the West Middlesex, and the price varies from 1*s.* per 1,000 gallons to 1*s.* 3*d.* per 1,000 gallons.

6739. Hampstead is at an exceptional elevation, and special pumping power is required. At all events the price is 1*s.* to 1*s.* 3*d.*, and they are not entitled to charge extra according to their Act of Parliament for anything but high service, which is 25 per cent., and that added to 9*d.* would be 1*s.*

6740. They are charging, are they not, in the districts of Wimbledon and Wandsworth 6*d.* per 1,000 gallons for extra high service?—That is very near their pumping stations; but if you take it at 8*d.* per 1,000 gallons, which would be about their lowest price, with 25 per cent. added for high service, it would come to 186,660*l.* a year. I have allowed in 1875 an increase upon that of about 50,000*l.* or 60,000*l.*, making a total of 250,000*l.* for the sale of water for trade purposes, and I am sure that that is below what the truth is, as it will actually be found. Then I have allowed for the sale of water to places on the way—10,000,000 gallons at 3*d.* per 1,000 gallons, which is a low price, and that is 45,000*l.* a year; and I have allowed for the sale of water to suburban districts beyond the metropolitan boundary, say 5,000,000 gallons at 6*d.* per 1,000 gallons; that is 45,000*l.* That is a low price, and those items come to a total of 1,048,333*l.*, assuming a domestic compulsory rate of 10*d.* and a domestic public rate of 2*d.* in the pound. Now as to the annual cost. In round numbers the cost, after deducting 1,000,000*l.* for available property, and adding interest and everything else which will accrue, so as to swell the cost before the introduction of the water, for 130,000,000 gallons, comes to 7,800,000*l.* The interest of that at 4 per cent. is 312,000*l.* The payment to the companies for existing dividends would be rather less, but I will put it at 500,000*l.*, and the cost of management 150,000*l.*, which is a large allowance, making a total of 962,000*l.*, showing a surplus of 86,333*l.* That surplus is equivalent to 1*d.* in the pound on the public rate, or 1½*d.* in the pound on the domestic rate, so that it shows that the people of London could be supplied after the expenditure of nearly 8,000,000*l.* with the softer water of Wales at 8½*d.*, for domestic supplies, and at 2*d.* for the public supply, making a total of 10½*d.*, or at 10*d.* for the domestic supply and 1*d.* for the public supply, making a total of 11*d.* in the pound. That is upon the rateable value, which I think is generally five-sixths of the actual rental. These rates are much lower than those charged for the supply of the hard water of the river Thames. The companies have a right to charge 1*s.* in the pound upon the full annual value, with extras for high service, for baths, for stables, and everything of that kind.

Metropolis Water Supply.

Statement showing Financial Results of obtaining Water from Wales, as on page 24 in pamphlet of November 1865, *revised March* 1868.

The total cost of the works on a scale, so far as the aqueduct is concerned, of 230,000,000 gallons per day, and reservoirs and pipes for the supply of 130,000,000 gallons, will be about 7,602,000*l.* To this must be added the cost of surveys, parliamentary expenses, interest on money during the construction of the work, the cost of superintendence, legal and general expenses, and these I estimate at about 1,083,000*l.*, by the time the works are completed, making a total of	£8,685,000
From this total I deduct the capital value of surplus property of the companies, to be released on the introduction of the supply by gravitation, estimated at	1,000,000
Leaving the net total	£7,685,000
The interest upon 7,685,000*l.*, or say 7,800,000*l.* at 4 per cent., is	£312,000
Add cost of management and working expenses, say	150,000
Payment of dividends to existing companies, and interest on their borrowed money	500,000
	£962,000

To meet these charges there would be received:—

Sales of water for trading purposes -	£250,000
Sales of water in bulk on line of aqueduct, and to suburban districts - -	90,000
Compulsory rate for *domestic supply*, at 10*d.* in the £ on 13,000000*l.* - -	541,667
Compulsory *public rate*, at 2*d.* in the £ on 20,000,000*l.* - - - - -	166,666
	£1,048,333

Surplus, 86,333*l.* = 1*d.* in the £ on £20,000,000

do. or 1½*d.* „ £13,000,000

6741. As I understand the calculation which you have now made, the result of a 10*d.* rate, and a 2*d.* rate, and the amount of water sold, would be about 1,000,000 and some odd pounds; what have you allowed for the invested capital of the companies?—500,000*l.* a year. I have taken their dividends. I do not remember exactly what their dividends were last year, but they are under 500,000*l.* a year. That includes the interest upon borrowed money and the dividends, which they divide amongst them. It is less than 500,000*l.* a year, but I have supposed that they were guaranteed the interest upon the money which they had borrowed, and the dividends which they now make, to the extent of 500,000*l.* a year.

6742. (*Mr. Harrison.*) Your calculation must also include all the expenses of maintenance and distribution?—Yes, it includes the expenses of maintenance and distribution, and the rates and taxes. The present rates and taxes come to about 40,000*l.* a year. I have allowed 80,000*l.* a year for rates and taxes. I have allowed 20,000*l.* for the outside administration, which is a very large allowance, and I have allowed 50,000*l.* for administration within the city itself.

6743. (*Sir J. Thwaites.*) Do your rates include the probable rating of your conduit and all your works?—Yes, I have ascertained what rating is paid in other places; but the rating is from returns made by the companies themselves and upon all that I have drawn the best conclusion I could.

6744. I am speaking of your conduit from the Severn; they would have a right to rate you in all the districts, would they not?—We should be liable to a certain amount of rate in gross and no more; and it would be divided along the line of country through which the conduit goes. It would be partly in respect of the water sold in London, partly in respect of the water obtained in Wales, and partly in respect of the water conveyed through the intervening districts; but you are only liable to the general rate which would represent the whole thing, therefore it would be spread over the whole district.

I have now come to the end of all that I wished to bring before the Commission, and I have only to thank you very much for the very kind and attentive manner in which you have listened to me. I may, perhaps, be allowed to say one word in conclusion with regard to the great advantage which I conceive would be conferred upon the inhabitants of London by the introduction of this superior soft water, and by the adoption of the principle which I have laid down, that the administration of the water should be in the hands of the inhabitants themselves, represented by a corporation or commission, or a board of works or board of health, for in my opinion it is as much the duty of the governing authorities to see that the poorest man has a good supply of water, as it is to see that the streets are paved and lighted, or that he has air to live in, for it is quite as essential to his comfort and his health. Everybody in a great community like this is dependent upon the supply of water brought to him. He cannot help himself unless he goes to a poisoned pump or to a neighbouring canal, or to the river Thames, and that only if he happened to be in close proximity. The example which was first set by the city of Manchester, and which has been followed by Glasgow and other places, of levying compulsory rates, has resulted in so much advantage and so great a benefit to the people at large, that I can only earnestly urge that particular view upon the Commission. I am led to make these observations, because his Grace asked me the other day whether it would not be possible to supply the existing companies with water which could be brought from Wales, and my answer was that it would be possible certainly, but that I had a very strong opinion against its being the proper mode of supplying the inhabitants, and my reasons are these. It is absolutely necessary that you shall have the means of levying compulsory rates. Water is as essential to people who live in a town as anything else. They must have it; they must either steal it or beg it, or get it in some way or other; and if they do not get it they are liable to disease and to other disadvantages which it is desirable to remove. You cannot give, or at least you never have given to any trading company the power of levying compulsory rates. You therefore make everybody pay as everybody ought to pay, and you get a large amount of income therefore without any individual hardship, and you are enabled upon the security of public rates of this character, to borrow your money at a lower rate than any private company could do. The average amount at which the money was borrowed by the Manchester Corporation for their water supply a couple of years ago, was 4*l.* 0*s.* 10*d.* per cent. The river Clyde trustees have recently been borrowing money at 3¾ per cent., and none of those great corporations at present are paying more than about 4 per cent. That is cheaper than the rates at which money could be obtained by any of the existing companies, and in the plan which I suggest you would pay nothing more than the interest of money borrowed at the lowest price and the working expenses.

J. F. Bateman, Esq.

11 March 1868.

6745. Can you state what is the form of the bond which enabled the Clyde trustees to borrow at 3¾ per cent.?—I cannot state that; but I was in Glasgow the other day, and the river Clyde trustees had just borrowed a considerable sum of money, I forget what it was, at 3¾ per cent. I am not sure whether the waterworks have borrowed at less than 4 per cent., but under their Water Act they have borrowed all their money, and I believe they do not pay more than 4 per cent. for it.

6746. Do they give in security the public rate, which they are authorized to levy?—Yes, the compulsory rates.

6747. (*Chairman.*) The money is borrowed in Glasgow at a varying rate probably?—They borrow from time to time as they require it, and of course at the price at which money happens to be at the time.

6748. It is frequently the case in Scotland, is it not, that if you borrow money you borrow it say at 4 per cent., and you afterwards pay interest varying as the Bank rate varies, and that is decided in Edinburgh?—I do not think that in this particular case it would be so. It would be at a certain rate for a limited period, for three years or five years, or something of that sort. I have here the Glasgow Corporation Waterworks return for the year ending May 1867, and I find that the loans on mortgage amount to 1,119,000*l.*, and the interest is 40,413*l.*, so that it is rather under 4 per cent. upon the whole amount of capital borrowed for the Glasgow waterworks. By my suggestion you would have further the advantage of constant supply at high service, and although I believe it would require some additional supply of water to that which is now taken, the consumption would be brought within narrower limits by proper supervision, and in any case it is the right mode in which the water ought to be distributed, and one which it has been impossible as yet to obtain from the existing companies. Those are all advantages which I think must be fairly taken into account even if the financial statement were against the introduction of the soft water, but as I have shown, you would by getting compulsory rates be enabled to obtain a supply of water of this superior quality, spending 8,000,000*l.* upon it, for a less charge per annum per individual than that at which it is now supplied by the existing companies.

The witness withdrew.

W. Rendle, Esq.

11 March 1868.

WILLIAM RENDLE, Esq., examined.

6749. (*Sir J. Thwaites.*) You are a surgeon, are you not, practising in Newington Causeway?—Yes.

6750. I believe you have held office in the parish of St. George the Martyr, Southwark, as medical adviser to the vestry?—Yes, I was medical officer to the parish for 17 years up to 1856, and medical officer of health during the three years after that: since that time, with little interruption, I have been a member of the vestry.

6751. During the discharge of those duties your attention has been called to the question of the deficiency of the water supply in that district, has it not?—Yes, frequently.

6752. Will you state to the Commission the result of those observations?—As to the deficiency of water, I believe it to be chiefly applicable to the supply as being intermittent. Complaints are numerous and incessant at our vestry, and our officers frequently note many places where complaints might be made, but are not, where the supply is deficient or altogether absent. The average quantity of water supplied to the people of London seems to be about 30 gallons per head per day, but that statement is extremely deceptive, for the class of people among whom disease usually begins, and upon whom it most heavily presses, do not get on the average—if I may take my parish as an example—more than from two and a half to five and six and seven gallons per head per day, and there is great waste. In my parish, which I give as a fair specimen of poor parishes, we have about 7,800 houses; of these 7,800 houses, 4,800 are houses which have usually been compounded for, and are occupied by persons of whom, perhaps, one half occupy only one room; the remainder of these 4,800 houses would be inhabited by persons occupying perhaps two rooms, but rarely more. These people are supplied, for the most part, with water to a not much larger extent than from three to four gallons per head per day. In order to bring pressure to bear upon the vestry to look into this and other matters, a circular was published, a copy of which I have before me. It was circulated among the vestrymen, and this is a paragraph contained in the circular. The vestry said in their agenda paper for that evening, "That the vestry "upon the recommendation of the sanitary committee "has in numerous instances ordered an increase and "better supply of water." My answer to that was "that 96 places had been visited by one of our chair- "men, Mr. Pocock, and myself during one afternoon, "when we went straight across the parish in the worst "parts without selection. We visited in all 96 houses, "and this was the result touching the water question. "Of the 96 places visited 42 require the inspector; "some are without any water supply, some without "water receptacles, some have broken or rotten "receptacles. All the houses, with two or three ex- "ceptions, are without covers to their butts, and so, "as one woman said, 'every bit of dust and dirt comes "in.' These, if cleansed, would become filthy "immediately from the foul atmosphere in these "close, filthy places; from drains and dungheaps close "at hand; from refuse, rags and dead animals wan- "tonly thrown by children into the open butts. In two "cases the small open casks were standing in pools "of liquid night-soil. In a very large number "the supply was quite insufficient. 15 houses with "181 inhabitants had water receptacles holding 456 "gallons—2½ gallons to each person. Pork tierces, "butter casks, small washing tubs, jars, and rotten "kilderkins, seemed to be the rule, except one side "of a street where no receptacles at all were found for "the people. An agent in St. George's New Town "(the chief fever haunt) says, 'There is not nor has "'been a sufficient supply of water about here; when it "'comes on, it generally dribbles and does not run "'in a full stream, and all the butts are too small for "'so many people.' With two or three gallons of "water it is of course impossible to keep house and "closets clean. The testimony of the people them- "selves ran thus:" One person said, "Our butt is so "rotten the water runs out as fast as it runs in." Another said, "We are obliged to beg water." Another said, "We are half the time without water." Others, "We have to go begging on Sundays." "We have only a nine gallon cask; we beg water "where we can." "I gave 6*d.* for my butt when I "came in four years ago." "We never had a butt "these five years." "We have no water, we beg it." And one said she "had hardly enough water to keep "herself clean with." These are a few of the many expressions we heard in our visit, given by the people in their own way. The water is on generally a very short time, 20 or 30 minutes, or, at the utmost, 40 minutes. The pipes are usually too small, or small ferules are introduced here and there underground into larger pipes, so as purposely to limit the supply. There is altogether too small a supply, and it has generally been most deficient where it is most wanted, that is to say, among people who are living in some parts of our parish 400 to the acre, or in other parts from 200 to 300 to the acre closely packed together. They do not get anything like water enough, and the modes of supply, the pipes, butts, in fact everything, are as a rule utterly insufficient for the purpose. In most cases there is only a small cask to receive the water; generally if there is a cask it is a very bad one, and in many cases there is none at all; there was one whole side of a street I recollect in my inspection in which they took the water from the tap; there was scarcely any yard, and the people had to keep their drinking water in basins underneath the bed or in one corner of the living room. That was in cases where the people occupied only one room. On Sunday the supply in our parish is altogether absent, or not worth speaking of. I understand that at this time, after a little pressure has been brought to bear upon the companies, there are about 8, 10, or 12 of our little courts which are supplied with water on Sundays; but it all comes through public taps, and does not go to the houses. I recollect some two years ago there was a very great outcry in Kent Street that the people were occupied half the Sunday (several Sundays) in going about begging water of their neighbours; many of the people said they usually got it at the public-houses; those who were near public-houses would probably get it from this source. The inspectors of lodging-houses, although they have more power than we have under their Police Act, to this very time frequently complain that they do not get sufficient water for the purposes of cleanliness in the ordinary common lodging-houses. As to the general supply, we have no complaints generally in connexion with the Lambeth Company; but against the Southwark and Vauxhall Company we are very frequently receiving complaints, not only as regards the intermittent supply, which is even at the times appointed for supply every now and then, as I am informed, altogether absent. Even in matters in which the company is bound to supply us constantly, as, for instance, in the hydrants that we water the roads from, and in the water waste preventers that we put up to prevent waste, and to afford constant supply in small courts, we and the poor people are frequently without water altogether. I understand from the evidence of our officers also, that when the large pipes, the mains I suppose, are empty of water, it is a very common thing for gas to get into the pipes and so to render impure the water which comes on afterwards.

6753. I understand your first complaint is that a very large number of poor people are insufficiently supplied with water, partly from the intermittent system which exists in the district and partly from the insufficiency of storage accommodation in the several houses?—Yes.

6754. You have spoken of casks and other receptacles; have you found that those casks or other vessels for holding water have been placed in a position near to closets where the water is likely to absorb any gases

which may be generated in cesspools and other places of that description, and is therefore likely injuriously to affect the health of the inhabitants?—In a district like ours, where in many cases the people have scarcely a back yard at all, where the houses are not quite back to back, but very nearly so, it is impossible, I believe, whether the casks are covered or not, but ours are mostly uncovered, so to place them that the water can be stored and be wholesome or even safe. I do not know whether the evidence has been before you, but in order to make it very clear and to show the power and danger of absorption by water that is stored in places where the atmosphere is unwholesome, I hand in a paper showing the usual absorbing power that water has in relation to certain gases. I may say that I gave this evidence in a printed report which I was requested to make to our vestry, which report I will hand in presently. I have corrected it up to the present time through my friend Dr. Odling; he writes me thus: "I send you the determinations of Bunsen, "which are considered to be most trustworthy." "1,000 volumes of pure water at mean temperature "dissolve 30 volumes of oxygen, 15 volumes of nitro- "gen, 3,232 volumes of sulphuretted hydrogen." This is a sewer and privy gas which we consider productive of fever, and which we can smell on entering many of the poorer places. I have tested this frequently by exposing a lead paper, which I have found darkened, proving the presence of sulphuretted hydrogen gas in the back yards. The water there stored will dissolve this gas in the proportion noted: "1,000 volumes of water will also dissolve "1,000 volumes of carbonic acid, and 782,700 volumes "of ammonia." Ammonia is principally a product of animal decomposition, developed in urinals and like places. This all indicates how dangerous the present state of things is in districts inhabited by very poor people, who are more or less filthy, partly from their own fault and partly because they have not the means and appliances for the storage of water; and it shows that water, when stored in such districts, cannot by any means of storage that you can devise be held to be safe as drinking water.

6755. Do you arrive at the conclusion that even if the vessels and receptacles were improved, it would not be safe to store water for domestic purposes, and that a constant supply under high pressure is the only remedy for that state of things?—I am satisfied as far as I can be certain of anything, that whatever it may be for the rich, who have comparatively large areas and paved court-yards and areas, and cleanliness in their houses, with fair means of ventilation about them, I believe it to be absolutely impossible for a large number of people in the poorer parishes of London to have wholesome water, if they are allowed the means of storage of any sort. In my parish there are 30,000 people in the poorest condition; they have hardly any back yards, and where they have back yards they are rarely paved, but are sodden and filthy with the soil running about; in some there are no dust-bins, the refuse being scattered about, moreover the houses are built much too close together, so that they have, except in case of storms, no sanitary draughts of air cleansing them out thoroughly.

6756. (*Sir B. Phillips.*) What would you suggest should be their means of supply?—Without any doubt they should have a constant supply of water.

6757. Do you mean by a standcock?—No, I think that mode is bad in every way, because the people would have to fetch the water, and there would be no supply in their houses.

6758. I understand you to say that it is impossible under existing circumstances for them to store water?—I do not calculate upon its being stored at all in vessels or cisterns or tubs, but that it should be brought by a tap into every house. I saw something like to this upon the property of Mr. Quick, the engineer of the Southwark and Vauxhall Waterworks. After he had published a circular and sent it to one of our vestries, as to the impossibility of having a constant supply among poor people, because they would waste it and misuse it, three or four vestrymen, myself included, inspected our own parish and other parishes in London, to observe what had already been done in the matter of a constant supply. This inspection is reported, pp. 11 and 12, Report on Constant Water Supply, written by me for and adopted by the parish of St. George's, Southwark, handed in. We found one court in our own parish near the Queen's Bench, belonging as I understood, and still understand, to Mr. Quick, where 16 houses were supplied upon the constant system, and had been so for seven years. The people there assured me that, excepting for a temporary purpose, such as cleansing the pipes or for repairs, they had never been without water night or day for about seven years. There was no particular waste going on; no water was laid on to the waterclosets, but nevertheless the waterclosets were cleaner than in places where it was supplied to them direct. The water in this court was turned on mostly by a screw tap from a pipe running behind the houses; it was one of the best conducted courts we had, which seemed to prove that the poor people took care of the water and valued it.

6759. (*Sir J. Thwaites.*) Have you turned your attention to the effect of soft as compared with hard water upon the health of the people?—I do not think that I can give direct evidence upon that point. I think the injury from hard water, undoubted I believe, is rather indirect; in the first place you cannot cleanse the body so well, the cleansing action of the soap is more or less defeated; the skin is covered with a greasy deposit from the decomposition of the soap. It is the same with regard to clothes: you cannot cleanse them nearly so well even if you use soap freely. There is another evil which can scarcely be over-estimated, you cannot cook so well; it is moreover not so economical in cooking. If you try to make a cup of tea with soft water and a cup of tea with hard water, you will find that your tea is not nearly so well worth drinking made with hard water as when made with soft. This of course is indirect evidence. However, I think it will answer the question just as well as if it were direct, because the same results come out, namely, incomplete cleanliness and bad cookery, and that these must be injurious to health is evident to all.

6760. (*Mr. Prestwich.*) Are there any public water taps in your district?—We have two water-waste preventers which the vestry has erected for the good of two of our filthiest courts; they are in pretty good action, and we have in some of the courts public taps, but these contrivances are at the best not much better than makeshifts.

6761. But they are not in general use?—No, they are not in general use.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 12th March 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS, C.B.	JOSEPH PRESTWICH, Esq.

S. C. Homersham, Esq.

12 March 1868.

SAMUEL COLLETT HOMERSHAM, Esq., examined.

6762. (*Chairman.*) You are a civil engineer?—I am.

6763. Have you specially directed your attention to Dr. Clark's process as a means of softening hard waters?—Yes, I have specially directed my attention to procuring spring water from the chalk, that spring water from the chalk being softened by Dr. Clark's process before it is supplied to the consumers.

6764. Can you shortly state to us the process of Dr. Clark for softening water, and then the steps which you have taken to apply it, and where, and what has been the result?—The process is simply putting a certain quantity of water saturated with lime into a reservoir. If the reservoir holds 900,000 gallons of water, in the first instance you put in the bottom of the reservoir 100,000 gallons of saturated lime water, and then add to this 100,000 gallons of lime water 800,000 gallons of spring water; I say spring water because it is essential for the process that it should be a clear spring water; a river water is not adapted for being softened by the process.

6765. Are we to understand that the lime water which you apply is in bulk as one to nine?—Yes, one-eighth to one-ninth in round numbers, sometimes it is a little more and sometimes a little less, according to the quality of the water, but as a rule about one-ninth is the average quantity required. The reservoir is then filled up with spring water, say eight-ninths of it, and the water as it is sent in to fill up the reservoir is sent in at a low point through three or four small apertures at a considerable velocity, so as to mix the lime water and the spring water intimately together; when the reservoir is filled the water is allowed to stand something like five or six hours, a sufficient length of time for the carbonate of lime that is formed by putting the lime water to the spring water to be deposited, and the water then becomes perfectly clear. The water when clear is either lowered into a reservoir situated below the reservoir in which it is softened, or if the water has to be delivered at a higher level it is pumped up to a reservoir at a higher level for the supply of the consumers.

6766. What time is occupied in mixing the lime water one-ninth in bulk with the water in the reservoir?—To give a practical illustration; at the last works which I recently made in the Chiltern Hills, we soften in one reservoir 100,000 gallons of water. The lime water is put in in half an hour, and the hard water is filled up in about three hours, making three hours and a half, and at the end of six or seven hours after that the water is clear, and ready to lower down into the reservoir below; so that altogether the softening in one reservoir takes some nine or ten hours. If the quantity be 1,000,000 or 10,000,000 gallons it is just the same, supposing your engine power to be as adequate to pump the larger quantity of water, as it would to pump the smaller quantity.

6767. Will you now state where you have applied this process, and with what success?—The process has been applied at various works. It was applied at the Plumstead works, which were opened in 1854, and the process was in operation there for seven years and gave great satisfaction.

6768. Is it in operation now?—Not at the Plumstead works; it was in operation there till 1861, when the works were sold to the Kent Water Company, and immediately upon the Kent Water Company purchasing the works they ceased to soften the water. It was not because the process did not answer, and it was very much against the wish of the consumers who were supplied with the softened water, but they did as a matter of fact cease to soften immediately they purchased the works. The Plumstead works were made, I should say, in opposition to the Kent Water Company, and they were in operation for seven years in opposition to them. They were then sold to the Kent Water Company, and when the Kent Water Company got possession of them, and not before, the softening process was abandoned.

6769. Are you informed as to the motives of the Kent Water Company in giving up this process?—No, it is impossible for me to be certain as to their motives. I know the engineer of the Kent Water Company, Mr. Morris, very well, and I understood at the time that they gave up the process simply because they did not choose to apply it through their whole district. The Kent Company supply a very large district independent of the district which they supplied when they bought the Plumstead Company, and they gave up softening, but of course I cannot tell with certainty what may have been their motive.

6770. What was the volume of water operated upon at Plumstead?—At Plumstead, latterly, we operated upon just about 1,000,000 gallons a day. I think from 900,000 to 1,000,000 gallons. In summer we frequently softened as much as 1,000,000 gallons.

6771. What was the size of your reservoir?—There were three reservoirs there, each holding 220,000 gallons, independent of the room below for the deposit. We could soften in each reservoir about 220,000 gallons, the reservoir holding about 250,000 or 260,000 gallons, the extra room being required to allow the carbonate of lime to deposit at the bottom of the reservoir.

6772. If your reservoir accommodation did not exceed 660,000 gallons, it would take you 15 hours to soften that quantity, would it not?—I will explain the process. Here are plans and sections of the three Plumstead reservoirs (*producing the same*). The spring water is pumped into a reservoir, the lime water being at the bottom of the reservoir. In this first work at Plumstead we used cream of lime instead of lime water; in all other works which I have made we use lime water. We made cream of lime the same as lime is slaked for whiting the ceiling; the cream of lime was forced by means of a cylinder among the water as the water was pumped up from the well; the lime mixed with the water, and then passed through what we call an agitator or a mixing apparatus (*producing a section*). The cream of lime and water, at the rate of about 1,000 gallons per minute, was forced together through a pipe, enlarged for a short distance, and having four plates with small holes in it. The cream of lime with the water went through the holes at a higher velocity than it did in the body of the pipe. Then it went on through another such agitator, and so into three agitators. The water then passed by means of a pipe into a catch reservoir, and any bit of flint or any small matter that might have mixed with the lime fell to the bottom of this catch reservoir. The water then proceeded on to another agitator, and finally went into the depositing reservoir.

6773. That process of dealing with a certain quantity of water, mixing it with one-ninth its bulk of lime, water agitating the water, and passing it into the reservoir occupies about 10 hours, does it not?—The filling of the first reservoir occupies about three hours and a half, and as soon as that is filled the second reservoir is filled.

6774. Then from the commencement of the operation, having your plant all ready, mixing your lime and then passing it into this pipe and through the agitator, so as thoroughly to mix it with the large body of water, and allowing the deposit to take place, and passing it into the reservoir, it occupies how many hours?—As soon as we had filled the first reservoir, and while we were filling the first reservoir we were intent on pumping the softened water from the second reservoir into the service reservoir, which was situated on Plumstead Common at an elevation of 170 or 180 feet above the works, and by the time the No. 1 reservoir was filled No. 2 reservoir was empty. We then filled up No. 2 reservoir, and at the same time emptied No. 3 reservoir, and by the time No. 2 reservoir was filled, No. 3 reservoir was empty, and by the time No. 3 reservoir was filled No. 1 reservoir was emptied, and ready to fill again.

6775. Those three reservoirs were found sufficient for dealing with 1,000,000 gallons?—Rather more than 1,000,000 gallons, but practically they supplied about 1,000,000 gallons a day of 24 hours.

6776. Supposing you had to deal with a larger body of water, are those reservoirs of a size that you would use, or would you increase the size of the reservoirs to adapt them to the larger quantity?—If I were dealing with 8,000,000 or 10,000,000 or 12,000,000 gallons of water a day I should certainly have an additional number of those reservoirs, or reservoirs of larger capacity.

6777. Would you multiply the reservoirs or increase their capacity?—I should increase their capacity; in the first instance I should make them very much larger, and the engine power would also be very much more powerful, but we should fill them relatively in the same time.

6778. Still keeping to the works at Plumstead, where you had experience for seven years, can you tell us what the cost of the application of this system of softening was?—Yes, I can tell it quite accurately. The total cost of the construction of those three depositing reservoirs, the lime apparatus, and the whole complete, was under 3,800*l.*, including the connexion with the pipes, the agitators, and so on.

6779. Do you mean that that was the cost of all the arrangements necessary for your softening process?—Yes, except in this, that we pumped the water from a well about 150 feet deep to the bottom of the well, and if we had supplied the water in its normal condition in its hard state to the consumer we should only have had one set of pumps, and should have pumped the water direct from the well to the service reservoir upon Plumstead Common, and that would have saved us some little expense in the first cost. To soften the water we had two sets of pumps. We had one set of pumps at the well which pumped the water into the softening reservoirs, and we had another set of pumps to pump the water from the softening reservoirs to the service reservoirs, from which it was supplied to the consumers, and as nearly as I can say that might have cost an extra sum of 500*l.* or 600*l.*

6780. That would be 600*l.* added to 3,800*l.*?—Yes, including the extra pump work.

6781. Is that an inclusive sum, or are there any other items of cost?—No, I think that is fairly the cost at those works. You will observe that the softening reservoirs are not covered. Now from my experience at those works I have never made any other works with softening reservoirs uncovered, and I should not recommend the water to be softened in uncovered reservoirs. It is quite as practicable to soften in uncovered reservoirs, as it is to filter in uncovered reservoirs, but pure spring water is of a very delicate character, and in hot weather many sorts of things settle upon the top of the water.

6782. What would be the cost of covering reservoirs of this size?—Those reservoirs would probably cost another 1,000*l.* additional to cover.

6783. Then about 5,500*l.* would be the total cost?—Yes, I should say if you calculate it at 6,000*l.* per 1,000,000 gallons, that would be the outside estimate for the structural works. I may also add with regard to filtering river water, that the structural works would have cost as much as those reservoirs, and as far as the pumping goes, you must take the water from the river, and pump up your water after it has been filtered.

6784. Will you direct your attention to the cost of working and the current expenses?—The current expenses at Plumstead were about 1*l.* 7*s.* per 1,000,000 gallons, for the cost of the lime and the labour, that is to say, the cost of the lime was about 1*l.* per 1,000,000 gallons, and the labour about 7*s.*, making about 1*l.* 7*s.* as the cost of the lime and the labour per 1,000,000 gallons.

6785. But there are other expenses besides the labour and lime, are there not?—I think not, the pumping is included, because although we pump from the well into the softening reservoir, and then we pump from the reservoir into the service reservoir, yet the total lift is no more. We raise water from the well, say 130 or 140 feet into the softening reservoirs, and then we raise it from the reservoirs another 150 or 160 feet into a service reservoir situated on Plumstead Common, but if not softened we should have had to raise it at once 300 feet.

6786. You move your agitator by means of steam, do you not?—Yes, but that is a very small matter. I think that the 1*l.* 7*s.* would quite include it; it is nothing of any consequence.

6787. Have you been able to form an opinion as to the application of this system to 1,000,000 gallons, or its application to a very much larger volume of water?—If you take spring water, which, as I have said before, is essential to the success of this process, you may apply it to any amount of water. It is much easier to apply it to 100,000,000 gallons a day than it would be to 1,000,000 gallons a day, inasmuch as the adjustment of the exact quantity of lime to the water is much more easily accomplished on a very large scale than on a small scale.

6788. Taking the supply to the metropolis as 100,000,000 gallons a day, have you formed any idea as to the cost of the works which would be suitable for dealing with so large an amount of water?—Taking 6,000*l.*, which I am sure is an outside estimate for the works to soften 1,000,000 gallons, of course it would be 600,000*l.* for the whole metropolis, at 100,000,000 gallons a day.

6789. What would be the area which you would require to carry out this system?—I have not calculated the area; I could do so; it is nothing very large; the works for that 1,000,000 gallons a day covered about a quarter of an acre. I should certainly say less than one-third of an acre, or perhaps say about one-third of an acre. Of course that is for 1,000,000 gallons, and that would be 3,000,000 gallons to the acre, or about 33 acres for 100,000,000.

6790. Have you calculated the cost of applying this system to the whole of the supply of London?—The cost would not be more than what I have given; on a large scale probably you may do it more cheaply rather than less cheaply, so that you may take 600,000*l.* as the cost of the structural works; the cost of lime and labour per 1,000,000 gallons would be 1*l.* 7*s.*

6791. Mr. Morris was examined here as a witness, and he states with reference to Dr. Clark's process at Plumstead, that he took possession of the Plumstead Works, where the process had been going on for some years, but he says, "We did not carry it on; we "found the whole thing so imperfect and so utterly "not to be depended upon, that we were obliged to "abandon it?"—I would say in answer to that, re-

S. C. Homersham, Esq.

12 March 1868.

siding as I did at Shooter's Hill at the time those works were under my charge, and having my attention specially directed to the works which, as I said, was for a period of seven years, that immediately the works came into the possession of the Kent Company they ceased to soften by that process, and they had no experience with it at all. Mr. Morris did not carry on the softening process for one hour, and therefore it is not correct for him to say that the process was troublesome, and that that was the reason he abandoned it.

6792. He says here that all the leaden cisterns in the district of Plumstead were found to be seriously affected, and some of them perfectly destroyed?—That is altogether erroneous. The softened water has far less action upon lead than the unsoftened water; softened water in fact has no action at all upon lead, and the unsoftened water may have a very slight action. I hold in my hand a report by the late Dr. Clark and by Dr. Smith, who both examined this point very carefully indeed, and this evidence of Dr. Clark's and Dr. Smith's was confirmed by Dr. Stenhouse, by Dr. Lankester, Mr. Dugald Campbell, and some other equally eminent men. What they state is this: "In order to ascertain whether the softened "spring water would take up any dangerous quantity of "metal from leaden pipes or cisterns, we kept this "water in contact with lead under precisely the same "circumstances as four other waters that were not "known from experience to have produced upon the "consumers any ill effects from lead. The contact "was continued long enough to permit a considerable "action by some of the waters. Of those tried, the "water that had most action on lead was the filtered "water of the river Dee, as supplied to the inhabi-"tants of Aberdeen. This water, which is about "half the hardness of the softened Watford water, "and contains about half the saline matter, took up "one-tenth of a grain of lead per gallon. The next "degree of action on lead was found in the Thames "water; one specimen from the West Middlesex "Company's water, another from the Lambeth Com-"pany's water, derived by them from Thames Ditton. "There was no perceptible difference in the action of "these waters upon lead. Each took up about a "half of the preceding water, or one-twentieth of a "grain per gallon. Next in its action on lead was "the New River water, which took up two-thirds of "what the Thames water took up, or one-thirtieth of "a grain per gallon. Tried in precisely the same "way as the Dee, the Thames, and the New River "waters, the softened Watford water showed to our "tests no action on lead, although those tests would "have detected in the water much less than one-"hundredth of a grain per gallon." I may state practically that I made the works as I said for the supply of Castle Howard with softened water, which have been in operation for a great many years. The water is pumped by a water-wheel for the supply of Castle Howard through a lead pipe, which is laid all the way up from the works, which are something like half a mile distant to the castle, and the cistern itself is lined with lead. It is a very large cistern, perhaps half as large as this room, and there has not been the slightest action either upon the lead pipes or upon the cistern. I was at the works a very short time ago, indeed within the last fortnight, and there is not the slightest action upon the cistern or upon the pipe. The late Earl of Carlisle, who took a great interest in the softening process (and it was through him that it was adopted at Castle Howard), had the water constantly examined when the works were first in operation to see if there was any action upon the lead by the water, so that nobody might be injured at the castle.

6793. Can you point us to any other place where this system has been applied to any considerable quantity of water?—The works where they are applied I can give you in order. There was the Castle Howard Waterworks, opened in 1858. Then there were the Caterham Waterworks.

6794. Of the latter I believe you have no experience at present?—They have been in operation ever since 1861, so that we have seven years' experience at Caterham, and we have added within the last twelve months 20 miles of pipe to that district.

6795. What is the amount which you supply from those works?—We supply Caterham, Godstone, Bletchingley, Nutfield, and Red Hill, a district containing a population of 24,000 persons.

6796. What quantity are you supplying now?—I do not know the exact quantity at the present time, but only last autumn our pipes were extended into Red Hill, and the works have been in use for the supply of Caterham, and Warlingham, and a large district around, ever since 1861. I do not know the exact quantity that we are softening per day. There we have no complaints, and in fact I may say positively that there is no action of that water upon lead. I have a report by Mr. Campbell, who has analysed that water most particularly for its action upon lead, and in it he states: "The action of the "softened water was tried in a very severe manner, "by exposing it for six days to bright scraped lead, "and likewise to ordinary lead, such as in pipes and "cisterns, only in each experiment the surface of "lead exposed was very much larger indeed than "would occur in practice; and on testing the water "afterwards by the most delicate tests I was unable "to detect a trace of that metal in either case, so "that this water may be said practically to have no "action whatever upon lead, which is not the case "even with many hard waters, although their action "is generally slight, and scarcely what may be termed "of a deleterious nature." We have practically supplied it to cisterns in Caterham lined with lead, and we find not the slightest action upon lead by that water.

6797. But you have made no calculation at all, have you, as to the cost of the works for dealing with the whole water supply of the metropolis, or as to the annual charge for working the system?—I have already said that 600,000*l.* would be the cost of the structural works, and that 1*l.* 7*s.* per 1,000,000 gallons would be the cost of softening the water, it might be rather less upon a larger scale.

6798. Are you sanguine as to the applicability of this system to the whole supply of the metropolis?—Certainly, there is no more reason why water should not be softened than that it should not be filtered, it is easier to soften water; I have had a great deal of experience in filtering water, and a great deal of experience in softening water.

6799. What do you do with the spent lime?—I have brought some of the deposit to show the Commission. We put in half a ton of lime and we take out in return 3½ tons of whiting, the most beautiful whiting you can possibly imagine. If you put it under a microscope you will perceive that it forms beautiful octohedral crystals perfectly white, and it is well adapted for cleaning metals, making soda-water, and most of the purposes to which ordinary whiting is applied; and if the process is applied in covered reservoirs, and proper care is taken with the whiting, I have no doubt that it will pay a very large proportion of the expense of the softening process itself.

6799*a*. Have you had it analysed?—Yes, I have had it analysed, and I have the analysis of it here. This (*producing a specimen*) is some whiting taken within the last day or two from the Chiltern Hills works. That is made not with cream of lime, but with lime water.

6800. Then it has been no source of expense to you but rather of profit to utilise this product?—I should say that the commercial value of that whiting is about 15*s.* or 16*s.* a ton, and I calculate that the value of the whiting would be equal to the whole cost of softening the water. Here is the analysis of the whiting by Mr. Campbell:—

"I beg leave to report to you the results of my analysis of a specimen marked 'The Caterham Spring Water Com-

pany. Whiting or precipitated chalk obtained in softening the water by Dr. Clark's process, December 10th, 1863.'

	In 100 parts.
Moisture	5·39
Silica	1·09
Oxide of iron, alumina, and phosphoric acid	0·94
Carbonic acid	40·39
Lime	49·40
Magnesia	1·50
Potash	0·49
Soda	0·74
Loss	0·06
	100·00

was submitted to low redness for some hours, but without any loss of weight, thus showing that it contained no organic matter; but besides this test the gas was passed for hours through proper solutions, to test for organic matters, but without exhibiting the slightest trace. This, together with the high per-centage of carbonic acid which it yields, would render it, I think, especially valuable for the manufacture of gaseous drinks."

6801. (*Mr. Prestwich.*) What do you consider to be the value of this whiting?—I consider it worth from 15*s.* to 16*s.* a ton. We have never sold it for so much, because it has never been worth our while to collect it in a proper manner, and put it before the public for sale. At Plumstead we used to sell the whiting for about 7*s.* a ton, but it was used by brickmakers. There was a great demand at Plumstead at the time those works were in operation for chalk to mix with brick earth for making bricks, and we used to get rid of it without drying it; men came and fetched it away at 7*s.* a ton, and that about paid for the lime. For every ton of lime that we put in, we took out 3½ tons, or rather more than that of this whiting. Say that the lime cost us 1*l.* a ton, we sold this for about 7*s.* a ton, three times that is 21*s.*, and there was the additional half a ton, so that we got a little more in point of fact for the deposit than we paid for the lime that we put in the water.

6802. Do you find a sale for it in those other localities where it is applied?—We shall do so. The Chiltern Hills works we have only just opened, and I have no doubt that we shall put up a proper apparatus there to dry the whiting. Whiting should be dry and clean, but it did not matter to the brickmakers whether it was clean or a little dirty; but from inquiries which I have made I am satisfied that properly treated it is worth certainly from 15*s.* to 16*s.* a ton.

6803. Do the waters of those five localities present any considerable difference?—There is a considerable difference in the qualities of the waters. At Castle Howard the original hardness of the water is 22·1 degrees, and it contains in solid contents per gallon 28·4 grains. The water softens down to 4·3 degrees, and the solid contents in the water are 10·75 grains. At the Caterham works the original hardness of the water is 18·74 degrees, and the solid contents per gallon 26·84 grains. The degrees of hardness when softened are 3·5, and the solid contents 9·84 grains. At the Herbert Hospital, where I should say the water is supplied by the Kent Company from their wells, the original degree of hardness is 22, and the solid contents per gallon 29·48, and when softened it softens down to 7½, and the solid contents per gallon to 15·1. At the Chiltern Hills the original hardness of the water was 13·25, and the solid contents in grains per gallon 21·6, and the water when softened was 2·2 degrees, less than 2¼, and the solid contents per gallon 8·24 grains.

6804. Then the result in different localities is different?—The result is different with different quality of waters; but when you get what I term the pure chalk water, the water got where the chalk is not covered with London clay, or interfered with by any superficial deposit, the quality of the water from the chalk is almost uniform; whether you take it at Hull, at Great Grimsby, or Bridlington, or Tring, or Watford, or Brighton, or any place where the chalk is not covered by a superficial deposit of London clay or plastic clay, you find the water almost of one uniform quality; sometimes it will contain one or two or three or four, more or less, grains of bicarbonate of lime; but that is the only difference that you find in the quality of the water.

6805. I am aware that there is no great difference in the quality of the water in different parts of the chalk; but my question was with reference to the result which you obtained after subjecting the water to your process?—After subjecting the water to the process, my experience is, that where the chalk has not been covered by London clay or by plastic clays, it almost always comes down to from 3½ to 2½ degrees of hardness. In the district south of London, if you take the North Downs, which supply the Croydon and Caterham works, and so on, it softens down to 3½ degrees; the Chiltern Hills water softens down to 2¼ degrees; the water taken at Watford, or St. Albans, or Redbourn, or Tring, softens from 22 down to 2·6 degrees.

6806. The Caterham Waterworks are on the lower chalk, are they not?—The fact is that at Caterham we go through something like 130 or 140 feet of gravel or more before we come to the chalk at all; they are on the top of a hill. We are 700 feet above the level of the sea, and we go through the chalk into the upper greensand. I for this purpose call the upper greensand anything lying above the galt clay chalk; probably geologists would call it the upper greensand. A great deal of our supply does come from the upper greensand; half of it comes from the chalk; and a large portion from a bore-hole that we have made into the upper greensand; we rather avoid going through the galt.

6807. Has the Caterham water been analysed?—Yes, frequently. I have an analysis of it here, made by Mr. Campbell, dated the 21st of July 1862, and it is as follows:—

"On the 14th of July instant I visited the Caterham Waterworks, and took specimens of the water, for the purpose of making a chemical examination of the same, from the reservoirs, just as it is supplied to the consumers, and I beg to report as follows:—

"The water was found to be at a temperature of 50° Fahrenheit. It had a fresh pleasant taste, was perfectly colourless, with a brilliant appearance. It is very well aerated, and gives no deposit whatever on standing.

"The total solid contents per imperial gallon of 70,000 grains, at 60° Fahrenheit, were found to be 8·96 grains,

Consisting of—

Mineral matter	8·64	„
Volatilized matter	0·32	„
Degrees of hardness by soap test	3·5	„

"The mineral matter was found to be of the usual composition of mineral matter in such water. The volatilized matter did not blacken on heating, indicating the absence of what is generally known as organic matter in water.

"As stated above, the hardness was 3½°, which is only about one-fourth to one-fifth of the hardness of the water now being supplied to any portion of the metropolis.

"Before concluding I may add that when taking the above specimens I spent many hours at the works examining carefully the way in which the softening process was conducted there, and I was much gratified both with the various appliances I saw and the truly substantial but yet economical way in which they were carried out."

6808. Have you also an analysis of the water from the Chiltern Hills?—Yes.

6809. Will you have the goodness to put in that analysis also?—Yes; it was made by the same gentleman, under date the 13th of March 1865, and is as follows:—

"Chiltern Hundred Waterworks Company.

"I beg leave to report to you the results of my chemical examination of a specimen of the above company's water received from you on the 28th ultimo.

"The water was contained in four Winchester quarts, and was perfectly bright and colourless.

S. C. Homersham, Esq.

12 March 1868.

"An analysis of the water gave as follows:—

Total solid contents, per gallon	-	20·16 grains.
Consisting of—		
Mineral matter	-	19·44 „
Volatilized matter	-	0·72 „
Degrees of hardness	-	13·25 „

"The mineral matter is of the following composition:—

Silica	-	1·44 grains.
Carbonate of lime	-	12·96 „
Magnesia	-	0·37 „
Chloride of sodium	-	1·17 „
Other salts of soda and potash	-	3·20 „

Nitric acid, a trace.

"There is neither iron nor sulphuric acid present in this water, the latter of which as sulphate of lime is so troublesome in boiler construction.

"When the above water is submitted to the liming process of Dr. Clark, a very beautiful, bright, and colourless water is the result, which gave as follows:—

Total solid contents, per gallon	-	8·24 grains.
Consisting of—		
Mineral matter	-	7·64 „
Volatilized matter	-	0·60 „
Degree of hardness	-	2·2 „

"I have ascertained with great care that for every 1,000 gallons of the spring water 80 gallons of saturated lime water made with the spring water are required to soften it to the degree of hardness stated above.

"The softened water was exposed to clean lead for five days at the rate of one gallon of the water to five square feet of lead, which is a very severe test, and the conclusion I have come to is that the softened water has no practical action upon lead.

"From the above results it will be seen that the softened water is exceedingly soft and free from organic impurities, and is of first-rate quality for all domestic uses as well as manufacturing purposes."

6810. Has this process been applied at Hull or Brighton?—No, it has not. I think it is very little known at Hull. I was at Hull about a fortnight ago, and then saw the well that supplies the town, and which yields from 4½ to 6 million gallons of water per day, and I found they had not applied this process there; they did not seem to have heard of it even.

6811. Has your process any effect also upon any organic matter contained in water?—I very much doubt myself whether there is any impure organic matter in the original water as it comes from the subterranean springs. I believe, if you take water from the chalk, put it in a covered reservoir immediately, and keep it covered, as far as wholesomeness goes it does not contain anything deleterious; but if water does contain any organic matter, and you apply the softening process to it to a great extent, you take down the organic matter.

6812. What has been the effect of it when tried upon river water?—I saw it tried upon a very large scale at the Chelsea Waterworks in 1850, and I have a copy of the notes taken by Mr. James Simpson, junior, at the time that the trial was made. I think something like 3,000,000 gallons in one operation were softened The effect was this, that if the water operated upon is filtered water, so that it is water itself clear before you apply the lime, the deposit settles quickly, and you have no difficulty; but if the water contains any clay, or is discoloured by a flood, as river water frequently is, the organic matter in the water, or whatever it may be which discolours the water, mixes with the crystals of the carbonate of lime and alters the specific gravity, and they do not fall down but keep floating about in the water. The result is, that you must filter that water after it is softened. There is no difficulty in filtering the water after it is softened. I have known this done at Manchester, at Hoyle's works; they softened the water by putting lime in the water on a very large scale. The water was invariably filtered after the lime was added to it, but they found no clogging up of the filter, and nothing to prevent the water being filtered after it was softened.

6813. You find more difficulty in applying the process to river than to spring water?—Yes, because the river water will not clear. The softening is just exactly the same, but to get the deposit out and get the water away clear is the difficulty.

6814. Is it attended with great expense?—Yes, with river water it would be attended with great expense; it might take 36 or 40 hours for the deposit to settle down to the bottom, so that you must filter as well as soften.

6815. That would tend to clog the filter, would it not?—No, I do not find that it tends to clog the filter. I say that is a most remarkable circumstance, that there is no clogging of the filter, or anything of that sort. The first place where I ever saw the process in operation was at Hoyle's works at Manchester. At the time I examined it they had had it in operation for some time, not so much for the purpose of softening the water as to clear it of organic matter. They are large printers, and they wanted to get the water clear again for some of the rougher processes. After they had used fine spring water, and had got it discoloured in some of their processes, they put a certain amount of lime with it, not so as to have any excess of lime, but just as much as would neutralize the bicarbonate of lime in the water, and then filtered it through a filter; they did so for several years, and they did not find the filter to be stopped up or fouled or injured in any way. I may state that for eight or nine years I have had this softened water passing through the most delicate water meters, but we have never had the slightest bit of fouling or injury to those water meters or to any pipe through which it has gone. I took out some pipes last autumn which the softened water had been passing through for something like five years, and the inside of the pipe was just as clean as the day it was put down.

6816. (*Col. Harness.*) If you applied the process to the Chelsea water would you prefer it filtered before softening or after softening?—I should prefer not to apply it at all, that is to say, I think river Thames water under any circumstances, whether you soften it or whether you do not soften it, is quite unfit for human consumption. But provided you had a choice it would require some experience to know what was best to be done. I could not say, but I think I should have it softened before it was filtered.

6817. (*Chairman.*) Would not your system of softening throw down all that was held in mechanical suspension?—No; when you deal with live organisms such as you have in the Thames water, and as you have in lake water like Loch Katrine and other lake waters, you cannot get rid of them by lime or any other process, the things will live notwithstanding.

6818. What is the proportion deposited as compared with the quantity of lime put in?—There are 3½ tons of chalk deposit for every ton of lime added to the water.

6819. (*Mr. Prestwich.*) Do you find it throw down anything besides lime and carbonate of lime?—In the waters which I have had experience of there has been nothing to throw down, the water was quite clear before we softened it, and quite clear after we softened it.

6820. In all the waters there would be a certain quantity of other salts. If there be bicarbonate of magnesia in the water, it will throw it down. As I have stated, the water supplied to the Herbert Hospital is softened, and I have here an analysis of the water by Mr. Abel, in a book published by Captain Galton, giving a description of the Herbert Hospital. It is as follows:—

"The water supplied by the Kent Company to the Herbert Hospital Waterworks contains 28·38 grains of solid matter per imperial gallon. The proportions of the principal solid constituents in a gallon of the water are as follows: carbonate of lime 15·95 grains, carbonate of magnesia 2·10 grains, sulphate of lime 6·12 grains, chloride of sodium 3·21 grains, organic matter 1·00 grains, total 28·38. The foregoing analytical results show that the

hardness of the water is very considerable; estimated by Dr. Clark's soap test it amounts to 21° of hardness; it was therefore necessary to submit it to Dr. Clark's softening process before it would be fit for hospital use. In the preliminary experiments with the water supplied to the Herbert Hospital, it was found upon examining the water directly after its treatment with lime water (*i.e.* as soon as it had become clear) that its hardness was reduced from 21° to 9°; when the softened water was left undisturbed for 12 or 24 hours the hardness was reduced to 8° and 7°. This difference is due to the circumstance that a small proportion of the carbonate of lime separates gradually from the water in a crystalline form. As the softening tanks at the Herbert Hospital works are so arranged that the softened water will remain in the depositing tanks at least 12 hours, it may be considered that the average reduction of hardness of the water supplied to the hospital will be from 21° to 8°."

6821. You have had great experience, have you not, in the supply of water from the chalk districts?—Yes.

6822. You were engaged I believe extensively in the experimental works at Watford?—No, I had nothing to do with the experimental works there. Mr. Robert Stephenson gave me the particulars of those experiments, but I saw nothing of them myself.

6823. Were those waters ever tried with this process?—Yes, frequently; and here is an analysis of that water from Watford, which softens down to 2·6.

Analysis of the evaporated Residuum of Batchworth Spring Water.

	Grains per gallon.		Degrees of hardness.	
	Original.	Softened.	Original.	Softened.
Carbonate of lime	17·60	1·65	17°·60	1°·65
Nitrate of lime	0·08	0·41	0°·05	0°·25
Nitrate of magnesia	1·42	1·65	0°·95	0°·70
Nitrate of soda	—	0·09	—	—
Sulphate of soda	0·50	0·50	—	—
Chlorides of sodium and of potassium.	1·30	1·30	—	—
Phosphates (precipitated by ammonia from acid solution).	0·28	0·28	—	—
Silica	0·82	0·57	—	—
Volatile matter, including some nitric acid.	1·00	1·15	—	—
Residue on evaporation	23·00	7·00	18°·60	2°·60
Subtract latent hardness (magnesium salts)			0°·95	0°·00
Sensible hardness			17°·65	2°·60

6824. (*Chairman.*) That is exclusively a chalk water?—Yes, that is exclusively a chalk water. There is one great advantage in softened water, and it is a great advantage, that if you put a quantity of this softened water into a reservoir open and exposed to the air, it will remain as clear and good at the end of six months as it was the day you put it in; but if you fill a reservoir with perfectly clear spring water from the chalk, and put it into a reservoir as clean as a china basin, the water, in the course of two or three days in the summer time, will become covered with masses of confervæ, then insects follow, and the water becomes putrid—not because the water itself has anything in it to cause this putridity, but because it contains bicarbonate of lime, and the spores of the confervæ brought in the air live upon this bicarbonate of lime, and form upon the top of the water large floating masses of living organisms, which soon begin to decay, and then insects appear upon them; in a very short time the whole of the floating masses on that water becomes putrid. I acted for a great many years for the Brighton Water Company, and we pumped the water into a reservoir under the race-course. You might say the reservoir was as clean as a china basin. There was no puddle in the reservoir, it was perfectly tight, and rendered inside with cement and lime whitened. The surface of the water in summer put into this reservoir within two or three days was one mass of growth of confervæ and insect matter, and other sorts of impure matter. Now, when you soften that water before you put it into the reservoir, it may remain there for six months, and is as good at the end of six months, excepting that it may catch dust and impurities from the air, but it does not putrefy, nor do any organisms form in the water or on the water.

6825. Applying your principle of action at Plumstead to the cost of the application of the system if applied to the metropolis, assuming only 100,000,000 gallons per diem, I find that it will cost, in round figures, 80,000*l.* a year?—That is, I suppose, provided you have nothing in return for your deposit. The actual cost is 600,000*l.* for structural works, and if you take that at four per cent., it would be more like 24,000*l.* If you take 600,000*l.* at 10 per cent., it would be 60,000*l.*, and at five per cent. it would be 30,000*l.* In your calculation you do not take anything into account for the value of the deposited chalk or whiting. The whiting, as I said, at Plumstead paid for the lime. Without drying it, or giving ourselves any further trouble than letting it go into a sort of receptacle to get somewhat hard, we sold it, and it was carted away for brickmaking at 7*s.* per ton. If it was properly dried I am satisfied it would pay the whole expense, including the interest of the capital for constructing the reservoirs.

6826. (*Mr. Prestwich.*) Have you tried any experiments as to the quantity of air in the water before the process and after the process?—I have. I do not find that the air is injured in the slightest degree. The quantity of gas in the water after it is softened is precisely the same as before it is softened. I hold in my hand an analysis dated May the 4th, last year, on this point, made by Mr. Campbell, at my particular request, with respect to the Caterham water. The water was supplied to Mr. Campbell on the 29th of April, and he immediately analysed it for the gaseous contents, and the contents of softened water, drawn from a consumer's tap, were as follows:—There were 7½ cubic inches of air in the gallon, and that consisted of 2½ cubic inches of oxygen gas and 5 cubic inches of nitrogen gas; in addition, the little chalk that was in the water gave ·75 cubic inches of carbonic acid per gallon, but the carbonic acid was in combination with the carbonate of lime. Chalk, to the extent of about three-quarters of a grain per gallon, is soluble in the water, so that after your softening you have three-quarters of a grain of chalk in the water. If you take water from Loch Katrine, and analyse the air in the water at the loch, and analyse the air in the water in Glasgow, you will find this remarkable difference, that the loss of oxygen gas in the water going from the loch into Glasgow is 10 per cent. In the proceedings of the British Association for 1861, page 94, Dr. Wallace, a Fellow of the Chemical Society of Glasgow, states his analysis of the gaseous contents of the water taken direct from the loch and of the water taken from the mains at Glasgow to be as follows:—At Loch Katrine it contained 7·5 cubic inches of air or gas per gallon. At Glasgow it contained 8·5 cubic inches of air or gas per gallon. But when you examine the quality of the air in the Loch Katrine water taken direct, and that taken from the pipes at Glasgow, there is this difference, the carbonic acid in 100 parts was 1 in Loch Katrine, and 4·5 in Glasgow; the oxygen gas was 33·4 in Loch Katrine, but it was only 29·9 in Glasgow; and the nitrogen gas was the same in both cases, 65·6, making 100. Persons acquainted with Loch Katrine, and with the quality of lake water in general, would easily account for that. Lake waters are full, so to speak, of organisms and decomposing organic matter, and the oxygen gas is destroyed by the decomposing matter, or it destroys a portion of the decomposing matter and forms carbonic acid gas, so that you find 4½ in the 100 of carbonic acid gas in the Glasgow water taken from the main at Glasgow, and you only find one at Loch Katrine; but you find the oxygen gas diminished in Glasgow to 29·9, although in the loch the water contained 33·4.

S. C. Homersham, Esq.

12 March 1868.

I have had very large experience for many years of water impounded in large reservoirs, and I have taken water from the reservoir that I was connected with at Todds Brook at the head of the Peak Forest canal. It there contained only two or three grains of mineral matter per gallon; but in the autumn, if you take a glass of water out of the reservoir, and look at it with your eye, you can count 20 different insects in it. My business frequently takes me to Manchester, and I have taken a decanter of the water at Manchester and looked at it, and I could see the living organism in that water by just holding the decanter against the light and looking at it; and if you take a globular glass vessel, such as the globes in which gold and silver fish are kept, and which assists in magnifying those insects, you can see them jumping about in all directions. In spring water from the chalk you never find organisms, or an insect of any kind. Those organisms live upon decomposing organic matter.

6827. The quantity of air in the two waters I see is much about the same, the Caterham water you say contains $7\frac{1}{2}$ cubic inches per gallon?—Yes, but the proportion of oxygen is larger in the Caterham water taken direct from the pipes.

6828. What is the quantity of oxygen in the unsoftened spring water?—I have not an analysis *pari passu* with the softened water now, but I have had it tried frequently, and it is exactly the same in the spring water as in the softened water; but you must always take this with my answer, that if you take water from a spring in the summer time and put it in a tumbler, the normal temperature being of 49° or 50°, and merely let it get warm by letting it stand in the sun till it is up to 60° or 70°, you have lost some of that gas out of the water from the mere increase of temperature. The water will not hold at a warm temperature so much oxygen gas in solution. The reason why the Thames smelt so bad some time ago was because in the summer time the temperature of the Thames varies from 68° to 72° or 73°, and there is a necessary loss of oxygen gas from the mere increase of temperature, and the organic matter decomposes more freely in hot weather than in cold weather. The decomposing organic matter also tends to deoxydise the water in the Thames, and this impure matter in solution in time comes to smell, as it did some two or three years ago.

6829. What is the reason for your expressing a preference to covered reservoirs?—Taking my experience at Plumstead those reservoirs were as well constructed as any reservoirs could possibly be for uncovered reservoirs; there was a wall surrounding them 77 feet high close in, and I found this, that in certain hot weather, when there was hardly any wind blowing, I would go round the reservoirs and see a heap of black something lying on the top of the water. I made the observation, the man has not been paying attention to his chimney, it is soot; but he said, no, there was nothing from the chimney, and on looking into the matter closely I saw that it was a whole mass of insects which had been sent against the wall of the reservoir and bounded back into the water; whole heaps of insects would fall into the water; also you cannot keep leaves out; in the autumn leaves will get into an uncovered reservoir, and impurities of a kind which you will hardly believe; large flies, tadpoles, and all kinds of things will get into the water if the reservoirs are uncovered, and all the softening reservoirs that I make now I invariably cover.

6830. (*Mr. Harrison.*) I gather from your evidence that your object would be to supply London entirely with spring water from the chalk, and to do away with the present supply taken from the Thames?—Yes, but when I say that I would do that, it would do itself if the Government would allow it to do itself. The only improvement that has been made in the London water supply has been made in the south of London, after the Plumstead works were made. The Plumstead works were made under considerable difficulties; we did not dare apply for an Act of Parliament because we felt sure that we should not get it if we did apply for it. The consequence was that the works were made by the inhabitants of Plumstead without an Act. The Kent Company at that time were supplying water from the river Ravensbourne, which is not only a very hard water, but is very impure in other respects. The new works were made, and as soon as we got into operation and got about 1,000 consumers attached to our mains, the Kent Company, knowing very well how many we had attached to them, inasmuch as most of our consumers were detached from their mains before they were attached to ours, sunk two wells, and they worked first one well and then another, not for the purpose of getting spring water for themselves, but for the avowed purpose of draining our wells, as their engineer said that would be the easiest way of getting rid of our competition; they put down very powerful engines, first one and then another, and worked them night and day for many weeks and months together, under the firm expectation that they were going to drain our wells, but still they did not affect them.

6831. My question was, whether your view was to take the water from those springs in substitution of the present supply from the river Thames?—In substitution of the present supply from the river Thames, certainly; but you must take this into consideration, that the New River Company now get their additional supply themselves from wells in the chalk. The Kent Company also now supply all their water from the chalk, although not taking it from the best source in the chalk.

6832. Have you considered at all the means of getting not only a supply equal to the wants of the present population, but to those of a largely increasing population?—Yes; I consider that to the tune of 10,000,000,000 gallons a day there would not be the slightest difficulty in getting it for the supply of Logdon.

6833. Have you made any estimate of the cost?—The cost is something inconsiderably small, you would be surprised to know at what a small cost you can get this chalk water. I will give a practical illustration. When we set out to make the Plumstead works, we set the works up to supply 600,000 gallons a day, and when we had driven our tunnels under ground and got 600,000 gallons, we did not trouble ourselves to get any more water, and the total cost was something like 2,500*l.* In the course of four or five years our consumption came very nearly up to 600,000 gallons a day, and it was requisite to do something. I said we must either drive some tunnels or put a bore-hole. I recommended a bore-hole, and we did so; we put down a bore-hole 18 inches in diameter, and about 500 feet deep. The total cost of that to the company was about 700*l.* to 800*l.* We contracted with Messrs. Mather and Platt to put in the bore-hole for 500*l.*, and we found the steam for working the steam-boring machinery, and some other expenses which might have brought it up to 700*l.* or 800*l.*, not more. We got by that bore about 600,000 gallons per day more, and that was the additional cost of getting another 600,000 gallons. Brighton has increased its water in this ratio; it is a very large ratio; Brighton is a very increasing place. I was connected with the company from 1846 to 1853 or 1854, when another company got an Act of Parliament, and we sold our works to them, and then my connexion with that company ceased; but in 1846 the company which I represented had 2,700 tenants; in March 1853 we had 7,260. In 1846 we supplied 800,000 gallons a day; in 1852 we supplied 2,500,000 gallons a day; and I should say that something like 3,000*l.* was the cost of increasing that supply from 800,000 gallons to 2,500,000 gallons. The readiness and cheapness with which water can be got from the chalk in well-selected situations would hardly be believed except you went very closely into the subject, and knew how readily it could be done. I have drawings of wells actually constructed that are in actual operation. Here is a drawing of the first one sunk at Croydon (*producing a drawing*). Croydon has been supplied from the chalk for a great many years, and that well supplies 2,000 gallons per minute.

S. C. Homersham, Esq.

12 March 1868.

There is a bore-hole 77 feet deep from the surface. For 20 feet from the surface there is a well 9 feet in diameter; for 10 feet deeper there is a well 6 feet 6 inches in diameter; then there is a bore-hole 24 inches in diameter for 24 feet deep; and then there is a bore-hole below that 12 inches in diameter for 23 feet, making the total depth from the surface 77 feet. The whole amount that the water is depressed, when the well supplies 2,000 gallons of water per minute, is 13 feet 9 inches.

6834. Do you mean depressed by the pumping?—While we are pumping at the rate of 2,000, gallons per minute the level of the water is lowered, the whole water line in the well is depressed 13 feet, but when we are not pumping, the water rises to the original level.

6835. You are constantly taxing the water in the chalk, and therefore you keep down that depression?—No, we do not tax the water in the chalk, because we take much less out of the chalk than comes into it. If you pour 50 gallons a minute into a basin and only take 20 per minute out, you will always have more water than you take.

6836. By reason of your pumping you have depressed the general water line 13 feet, have you not?—No, that is not so; when we are not pumping the water stands at the same level as it did at first. While we are pumping this particular well at the rate of 2,000 gallons per minute the water level is lowered 13 feet 9 inches; but when it is once lowered 13 feet 9 inches it gives 2,000 gallons per minute, and you may pump it night and day and it does not lower any more. And if you leave off pumping for a short time it rises again to its original level, and you have not made any permanent depression. I was at Hull the other day, where the depression when pumping is something like 35 or 36 feet; from that well they get from 4,500,000 to 6,000,000 gallons per day, that is to say, in summer they require nearly 6,000,000 gallons, but in winter they do not require more than 4,500,000, therefore they take out of the well only what they require, and they only depress the water level when pumping some 35 feet.

6337. (*Col. Harness.*) What is the level of the surface of the well with regard to high-water mark?—It is from 80 to 90 feet above high-water mark at Croydon. I am now pumping from a well in the Chiltern Hills, where the water stands at 470 feet above high-water mark.

The witness withdrew.

Adjourned to Wednesday next at 12 o'clock.

Wednesday, 18th March 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS.	JOSEPH PRESTWICH, Esq.

THOMAS CROWTHER BROWN, Esq., examined.

T. C. Brown, Esq.

18 March 1868.

6838. (*Chairman.*) Are you a native of Cirencester?—Yes, I have lived in the district all my life. I have no personal interest at all in this question, but I have for many years as an amateur studied the chemical and geological features of the present case, and for 23 years have kept a daily register of the rainfall at Further Barton, one mile from Cirencester. I have brought with me a little map of the district to which my evidence particularly refers, and you will see by referring to it that it embraces the valleys of the Churn and the upper part of the Thames, and I have drawn on the map lines which are supposed to be the watershed, because on the one side we have the Colne, and therefore I assume that one-half of the area of the watershed belongs to the river Colne, and I assume that the other half belongs to the river Churn, there being a ridge of hills which separates the two sheds, and on the other side of the hills it is the same. There is the Stroud river which drains to the west, and I have served that in the same way. I only point that out to show that my calculation is upon the area inclosed by the two watersheds.

6838*a*. Have you the result of the gaugings to which you have referred?—Yes, and I will hand it in. The first is a monthly register of the rainfall at Cirencester from the year 1845 to 1868, and I have also given the yearly average of 30 inches, and it contains the monthly averages under the separate years, and the variations in the rainfall.

6839. Are those results from one gauge, and at the same point?—Yes, from one gauge, and at the same point. I have also prepared a paper showing the total amount of rainfall in that area, and that is a calculation which I believe you will find to be correct:

CALCULATION of the annual and daily RAINFALL in the district witness treats of, and the whole area drained by the rivers Thames, Swill Brook, Churn, Coln, Lech, Windrush, and Cole.

Average fall of rain 30 inches.

Square feet in 1 acre - - - - - -	43,560	being cubic feet of water 1 foot deep.
	43,560	add 1 do.
	21,780	6 inches.
	108,900	cubic feet of water per acre per annum.
	6	gallons per cubic foot.
	654,400	gallons per acre.
	640	
	418,176,000	gallons per square mile.
	90	square miles.
	365)37,635,840,000	total gallons rainfall on 90 square miles.
Average daily rainfall on 90 square miles - -	103,115,700	
	4	this area being about ¼ of Cotswold Hills.
Total daily rainfall of district drained by Thames, Churn, Coln, Lech, and Windrush.	412,462,800	

I begin by taking the superficial feet contained in an acre, and then calculating it at one foot in depth. I have given the cubic feet for one foot, and I have added another cubic foot for two feet and a half of that quantity again to make up 30 inches of rainfall for the year. The number of cubic feet multiplied by six gives the number of gallons per acre, and that amount multiplied by 640 acres gives the number of gallons per square mile. The number of square miles I calculate to be 90, and that multiplied by 90 gives the total rainfall of the district which I refer to, and that you will find amounting to 418,176,000 gallons. Having given the total rainfall, which is an enormous quantity, as you observe, I wish to explain the way in which it is disposed of and what becomes of it. It is disposed of, first, by rivers, as in this case the Churn and the Thames are the surface drains; secondly, by evaporation. That evaporation is confined to the surface, for excepting in very warm weather, when the heat assists the evaporation, it is merely surface evaporation, and that varies, as we very well know, very much in summer and winter. But in addition to evaporation is the action of living vegetables taking up water by their roots during the period of their growth, which appears to me to be an enormous quantity, but which it is impossible to ascertain. We know perfectly well that vegetables depend upon water, and take up water, and disperse an enormous quantity in the atmosphere; it is disposed of, thirdly, by irrigation. In those pretty considerably descending valleys of the Cotswolds it is a very general practice to water the grass meadows, and those meadows are flooded for a time, and of course a great deal of water is lost in that way, because there is evaporation going on there, besides the stimulus to the plants, and in addition to that a portion of that water descends by gravitation into the soil; fourthly, it is disposed of by gravitation into the lower strata, that is another element which we cannot ascertain, but which I believe is very great indeed, for I believe all of what we call the impermeable beds, the clays are only so to a certain extent, and that they stop water in quantities; but there are also besides that large quantities passing through into the lower strata. For instance, in the Cotswold Hills, on the upper oolite where the rain falls, it descends till it comes to the fuller's earth, and when it comes to the fuller's earth a great deal is thrown off, no doubt, with the clay, but other portions pass through that fuller's earth into the lower oolite, and there we know there is no difficulty, it will go into the sands of the lower oolite, and perhaps only find a stop in the lias beds. Another great loss is by floods. When we have great rains in winter there is a great deal of surface water thrown out and that passes rapidly down the valleys and flood) the Thames and all the valleys connected with it, and is carried off and cannot be arrested; there are no facilities for making reservoirs to arrest it; and besides that the flood water is very impure, the flood water may be considered as a scavenger, for it carries everything that it finds on the surface of the earth in its flood. I next wish to explain the strata and soil of the district.

6840. Let me ask you whether you have taken any means, or have observed any other person who has taken means, to ascertain the net result of the area which you have now described, that is to say, after

allowing for evaporation and absorption, what the net result is which finds its way into the surface rivers; has that been gauged by yourself or any other person to enable you to judge as to the quantity due from that district?—Yes, I have had an opportunity of reading the evidence of Mr. Taunton on that subject before the Rivers Commission, and as far as that goes his gauge of the river shows how very little of the rainfall is carried into the rivers, and also how untrustworthy the gauging is. Now Mr. Taunton states that he gauged the Thames at Buscot in 1864, and he found only 1,166,000 gallons passing the Thames at Buscot, and he also gauged in 1854 the Coln at Fairford, and that he made to pass daily 1,692,000 gallons. I think nothing can more clearly show how untrustworthy the gauging of rivers is than that, for this larger amount is only from one river, the Coln, whereas the other, of the Thames at Buscot, includes the Thames proper, the Churn, the Leach, the Coln, and the Cole; so that I cannot answer the question of my own knowledge; but from what I find from others I think it is very difficult, indeed I may say almost impossible, to ascertain what portion of the rainfall does get into the rivers, there are so many circumstances to hinder the proper gauging of rivers. I will now proceed to explain the nature of the strata and soil of the district, because that has a very important bearing upon what I shall have to say hereafter; and, first, as to the chemical nature of the soil, I will not say that I can give you exactly what a chemist does, but it is very nearly correct. The soil of the district contained in the map which I have handed in is composed of about 45 parts of lime, 45 parts of clay, and 10 parts of silex, that is the surface soil. This soil readily absorbs the greatest rains, and the water descends by gravitation until it is arrested by an impervious stratum. The great stratum of the fuller's earth placed between the upper and lower oolites is the main stopper to the descending water. But not only is this bed merely a partial stopper, for it has so many faults in it that vast quantities of water pass at those faults into the lower oolites, and ultimately into the sandbeds resting on the lias, and from thence probably into the sea. I have here a little section (*producing the same*) which I had for a great many years when I was a director of the Cheltenham Great Western Railway; it is a section made by the resident engineer of the present tunnel of the Great Western Railway, showing the fault. Now it is obvious that water descending through this stratum has a vent somewhere, and therefore we may say that but a very small portion indeed of the rainfall is turned out by the fuller's earth beds; and I know of other faults myself. Besides the fuller's earth the upper beds of the upper oolites have numberless local beds of clay, as the Forest marble and the Bradford clay, none of which are absolutely impermeable, but being near the surface they throw out water during great rains and supply the winter wells. Thus it is impossible to look to the total amount of rainfall as a source of supply, the rivers take but the smaller part of it, the rivers only exist in valleys having springs. Some of the Cotswold valleys are dry. The Churn owes its very existence to this coating of fuller's earth, which holds the water in its descent from its first source, and the springs from the fuller's earth cause that river. The next valley is a dry valley which runs down to the Thames, there is no water in it, and there never is any water in it, it never cuts a spring. I now propose to come to the subject of the dip of the wells, and will hand in the following table, which shows the winter and summer supply of the wells at Cirencester.

Rise and Fall of Water at Cirencester in the Gravel Bed.

6841. Will you be good enough to explain the sense in which you use the term "dip" as applied to a well?—The dip of the deep well of 100 feet deep is an absolute dip—the depth of the water in the well. The dips of the other two wells which are in the gravel bed under the Churn are really dry dips, that is to say, the dip is taken from the surface to the water. That equally shows the rise and fall, but we have no means of knowing the depth of the water in that gravel bed. Two of those wells as I said are sunk in the gravel bed at Cirencester about 20 feet deep, and those underlie the river Churn. This bed of water has never been fathomed. The rule is to sink as deep in the gravel beds as possible, and in the driest seasons such wells never fail. It is an unseen underground river passing into the Thames by gravitation, that is evident, as it rises about 600 feet above the sea and descends 300 feet, so that there is a constant passage of water in that gravel bed. There is no doubt that the gravel bed rests upon clay beds, the fuller's earth, or the Forest marble clays, which latter appear as they approach the valley of the Thames. This gravel bed is supposed not to exist in the upper Cotswolds, where the beds of the fuller's earth throw out the springs, mainly supplying the Churn. I may here point out a singular circumstance, but which bears on the question of the loss of the water of the rainfall. The great loss of the river water occurring near North Cerney, four miles from Cirencester, probably arises from the commencement of the gravel bed, and it there leaves the river, and the water is carried in what I call an underground river to the Churn near South Cerney, where a beautiful spring flows constantly, called the Boxwell spring, which is clearly an outlet of that underground river in the Churn valley gravel, and calculated to thrown out more than 1,000,000 gallons per diem. At this point the Oxford clay appears, and is the probable stopper, causing the outburst of this Boxwell spring. The chemical composition of the oolitic beds referred to is

T. C. Brown, Esq.

18 March 1868.

the cause of the purity of the water in the wells, for not only are there no mineral substances to make it a mineral water, but the discovery of Mr. Way the chemist has proved scientifically what the facts exhibit, namely, the power of such a soil, especially in the clay, to arrest all feculant matter, and allow the rainwater which is impure passing through this natural filter, to descend into the lower strata in a pure state. It is the nature of the surface soil in the district in question that gives it such advantages over sandy soils, or silicious gravel beds, such as you have about London, and it is this feculant matter that provides nourishment to the roots of vegetables in the surface soil, and is indeed their manure. There is no doubt that all carboniferous and nitrogenous matters are thus beneficially disposed of, and preserve to us the green earth through a long time, and thus prevent that malaria which would inevitably arise where there are decomposing vegetable and animal matters, and which during decomposition is thrown into the atmosphere. The want of carrying out in towns the immediate removal of those decaying matters, but allowing them to decompose in sinks, and drains, and foul courts, is the real cause of fevers, and prevents the influence of the otherwise constant restorative powers of pure air and pure water on the human system. As a proof of the purity of the water, the following analysis of the water from wells by Mr. Church, the chemist to the Royal Agricultural College, Cirencester, will afford a proof of the correctness of the foregoing reasoning. This water was the Churn water from a gravel bed 10 feet under the surface-made soil of Cirencester, the wells being sunk 10 feet in the gravel.

Mr. Church says with regard to the Boxwell springs that the water is excellent in colour and taste, containing scarcely a trace of organic matter and no nitrous acid; that it is the best water he had examined from Cirencester, being perfect for drinking and cooking; and the analysis of two wells at Cirencester show that the water was completely free from all organic impurities. Those were Churn valley waters, but the strata of the Thames proper which we are considering, and through which the rainwater passes, is chemically the same, and no doubt a like purity would be found in its well water, that I think is unavoidable. It now appears desirable to refer to the operations of the Thames and the Severn Canal Company, as bearing upon the question. That company has 9 miles of summit level of canal, about 350 feet above the sea, falling westward to the Severn and eastward to the Thames. In order to keep up the requisite depth of water in the canal it employs two means, first, an engine at the Thames head raising every 24 hours 3,000,000 gallons of pure water 63 feet high from the fuller's earth; and, secondly, a feeder from the Churn at Cirencester, the quantity of which I have not ascertained. There are other small sources, as, for instance, where in cutting the canal they met with land springs; but those are inconstant in their flow. I have now stated to the Commission most of the facts, and although, properly speaking, it is my business only to give to you such facts as I am possessed of, yet I deem it the most important part of my duty to communicate the conclusions which I have come to, founded on those facts, especially as they form the very basis of the practical result which I imagine to be attainable. First, I need hardly point out that the rainfall of the district, if available, would be far more than sufficient to supply all the wants of London with water, to the amount of 100,000,000 gallons per day; secondly, notwithstanding that I am compelled to conclude that from the losses by winter floods, by gravitation into the lower strata, by evaporation in summer, by the quantity taken up by plants, by the quantity removed by the river, by the quantity passing into the gravel beds, and by the irrigation of water meadows, from those combined sources water in sufficient quantity to supply all the wants of London cannot be obtained from this watershed of the Cotswold, and if obtained it would not be pure water; for it is obvious that these difficulties interfere, namely, the use of water in the mills, in irrigation, and in supplying water to the whole district, it would dry up the wells, and it would be impossible to compensate all the claimants; my conclusion is that the question in this shape may be instantly dismissed. I now come to explain a plan which does appear to me to be feasible. The water supply of London is now provided by several water companies. To dismiss them altogether and draw one ample supply, as it has been talked of, say from Plinlimmon or Bala Lake, appears to me impossible, not only in the cost of compensation, but in the enormous first cost of bringing water 200 miles, and in the repairs, not to say the deterioration of the water by passing through such a length of pipes, but also from the injury arising from open reservoirs; altogether those, to my mind, are fatal objections to such a scheme. But my plan is exceedingly simple, and although I contemplate its application only to the Thames watershed of this district, yet it may be equally or even more applicable to other districts nearer London, possibly the chalk district. For instance, there is the Hungerford river, which is but little used, I believe, either for irrigation or mills; but this I leave of course to the Commission to consider, if they entertain my idea. If they entertain my idea, Mr. Prestwich, one of the members of the Commission, more than any man, perhaps, is competent to settle the source from which water should be procured. I am not a great geologist, I am only a local one, and my plan is this, to supply London with pure water for drinking purposes only. The evidence which I have before given may be now applied to show that pure water can only be obtained from wells, but that any soils composed of lime and alumina are perfect filterers, that there would be no difficulty in procuring from 6,000,000 to 9,000,000 gallons daily from the upper Thames district by pumping, and then conveying it to London; that the distribution would be readily, I believe, undertaken by the present water companies, probably by means of second tubes; that the general supply of other water to London would be continued by those companies as at present; that the measures now in operation to prevent the contamination of the Thames and its tributaries will ensure a supply of purer water than that which is at present supplied; that there are no difficulties which may not be easily overcome in carrying out this scheme at a moderate cost, from the fact that the Thames and Severn Canal Company are at this moment pumping 3,000,000 gallons of water daily from their well, and notwithstanding that the Thames is at this moment, as I saw yesterday only one mile distant from that engine, full of water. No doubt that arises from the first sources of the Thames being superficial clay beds throwing out the water, whereas the water pumped up by the Thames and Severn Canal Company is from the fuller's earth, which is much deeper down. That shows what could be done by that company in the district of its summit level, a level of 350 feet above the Thames at London Bridge, and any proposition to that company to find water it is not unreasonable to suppose would be entertained, when we know that that company, from its declining traffic, incident to the introduction of the railways, made proposals to Parliament in 1866 to convert its summit level into a railway It should also be borne in mind that in the Great Western Railway there now exists a viaduct from this very canal to Paddington, descending by most gradual gradients, and that it might be feasible on this viaduct to lay down pipes to London by arrangement with the Great Western Railway Company. The water would flow to London by gravitation, and were it not for friction it would rise to a level in a fountain in London 350 feet high I have only now just to give a summary or recapitulation of my plan, and perhaps the Commission will excuse me in detaining them so long. It is, first, to improve the quality of the Thames water by sanitary means; secondly, to continue the general supply of London by the present water companies; thirdly, to supplement this supply by pure water obtained from wells; fourthly, that the Thames upper

T. C. Brown, Esq.

18 March 1868.

sources are adequate to furnish from 6,000,000 to 9,000,000 gallons daily without disturbing the existing state of things; fifthly, it is possible that other sources nearer London may be found; sixthly, it should be remembered that pure water is not liable to decomposition like rain or river water. I hope the Commission will excuse my perhaps travelling a little out of the record, but I could not put all my ideas on the subject which I was asked to give evidence upon without going so far as this; and I have no doubt that when the Commission come to study the evidence which I have given, they will then be able to judge of what it is worth. I shall now be most happy, in addition to what I have already stated, to answer any questions which it may please any member of the Commission to ask me. What I have given is my simple report.

6842. (*Mr. Prestwich.*) What is the level of your rain-gauge above the sea?—It is about 400 feet. I am about 60 or 70 feet above the town of Cirencester, the town is therefore 340 feet above the sea.

6843. Do you know any other gaugings of the Thames and the Coln besides those of Mr. Taunton?—No.

6844. Have you gauged any of the springs in your district?—I tried to gauge the Boxwell spring, which is very near the union of the Churn with the Thames, but I did not succeed. I have therefore assumed Mr. Taunton's estimate of 1,000,000 gallons a day, and I believe that is correct; but there are a great many other springs in the Thames valley between the pump of the Thames and Severn Canal Company and the Thames at Cricklade.

6845. Do you know the level of those springs above the sea?—Very nearly; there is a gradual fall from the summit level, which is I think 350 feet, of about 80 feet to Cricklade.

6846. That would give the limits of the principal springs I suppose?—Yes.

6847. Are those springs permanent, and uniform in their delivery?—The Boxwell spring is permanent, the spring that filled the Thames yesterday is not permanent, it has a very superficial bed of clay that throws off the water, and it is generally dry in summer.

6848. Have you had the water in the various springs analysed?—Yes, I have handed in the Boxwell spring analysis by Mr. Church.

6849. You stated his opinion, but have you got the exact chemical analysis with you?—I could not lay my hand on Mr. Church's paper, but I copied it into my pocket book, and I have given you the substance of it.

6850. We should like if possible to have the exact analysis?—That I cannot give you.

The witness withdrew.

Captain Edward Burstal further examined.

Capt. E. Burstal.

6851. (*Chairman.*) You are the secretary to the Thames Conservancy Board, I believe?—I am.

6852. As appears from the evidence of Mr. Thorp, the deputy chairman of the Conservancy Commission, you have served notices, have you not, upon all the towns upon the banks of the river Thames, to the extent of your jurisdiction?—Yes.

6853. And I believe on the receipt of those notices certain difficulties arose as to what was the intention of the Thames Conservancy Board with regard to the degree of purity that they intend to insist upon, or that the Act could authorize them to insist upon?—I may state that the board were desirous of being able to form a correct opinion as to what should and as to what should not be allowed to come into the Thames, and with that object in view they considered it desirable that they should apply to three eminent chemists, Dr. Frankland, Dr. Letheby, and Dr. Odling, for the purpose of getting a report from those three gentlemen as to the standard of purity of the sewage water when defæcated, for being admissible into the Thames. Those gentlemen instituted a great number of inquiries, and the result has been a report which I will now hand in.

The same was handed in, and is as follows:—

Thames Conservancy,
41, Trinity Square, Tower Hill,
August 6, 1867.

Sir,

I am directed by the Conservators of the River Thames to request that you will report to them, conjointly with Drs. Frankland and Odling, whether fluid which has been mixed with sewage can be so purified as to be admissible into the river Thames; if so, in what manner it may be done, and to fix a standard of purity, with such observations as may be deemed necessary.

I am, &c.,
(Signed) E. Burstal,
Secretary.

H. Letheby, Esq., M.B., F.L.S., &c.,
London Hospital.

Ditto to E. Frankland, Esq., F.R.S., &c., Royal College of Chemistry, 315, Oxford Street.
Ditto to Dr. Odling, Bartholomew's Hospital, E.C.

Report on the Treatment of Sewage for Purposes of Defæcation, and on the Quality of Defæcated Sewage Water that may be permitted to enter the River Thames.

(*Received 4th March* 1868.)

Gentlemen,

In accordance with your reference of the 6th August last to the effect "that we would report to you whether "fluid which has been mixed with sewage can be so purified as to be admissible into the river Thames, and if so, "in what manner it can be done, and to fix a standard of "purity, with such observations as may be deemed necessary," we beg leave to report to you that we have visited the towns of Croydon, Rugby, Carlisle, Worthing, Leicester, and Hertford, for the purpose of ascertaining what are the practical results of the defæcation of sewage by irrigation, and by precipitation with lime, and we find that in respect of the former treatment of the sewage the operation is very successfully performed at Croydon, where the sewage from the outfall at Beddington, amounting, as we are infor med, to from 2,000,000 to 5,000,000 of gallons per day, is, after being filtered through shingle to keep back the coarser matters, distributed by means of open channels upon about 370 acres of land. The land is very porous, consisting of a subsoil of coarse gravel, and the crops raised upon it are chiefly rye grass, which is used for the most part in a green condition for feeding cattle. The water discharged from the land after irrigation and percolation through the soil is remarkably improved in quality, and may, we think, be safely discharged into any running stream.

At Rugby, Carlisle, and Worthing the processes of irrigation were not such as to enable us to form a very positive opinion of the quality of the outfall water, as it disappeared to a large extent into the ground; but the samples which we were able to collect were so far free from objectionable quality that they might safely be admitted into a proper volume of running water.

The sewage from one district of Croydon is discharged upon clay land at Norwood, and except in this instance and perhaps also at Worthing the soil appeared to be especially well suited for the reception of sewage by irrigation, for it was so porous from its sandy or gravelly nature that the water freely percolated it and was thus easily defæcated.

The conditions in fact which appear to us to be most favourable for defæcation of sewage by irrigation are:—

1st. A porous soil with good subsoil drainage.

2d. An outfall into a moderately large volume of freely running water; as, for example, a volume of not less than eight or ten times the volume of the defæcated sewage water.

3d. A considerable area of ground, in order that in times of heavy rain and during the growth of crops there should be ample means of disposing of the sewage. The area for the reception of the Croydon sewage at Beddington appears to be sufficient for the purpose, and it amounts to about 80 acres per 10,000 of the population.

The second process for defæcating sewage by treatment with hydrate of lime we saw in operation at Leicester and at Hertford. It consists in the addition of from 12 cwt. to a ton of lime, in the condition of a thin liquid, to each 1,000,000 gallons of sewage; and at Hertford there was also used about 50 lbs. of chloride of lime. The sewage mixed with lime and well agitated was permitted to flow through long subsiding tanks, where the suspended matters settled; and at the end of the tanks the clear water ran off

Capt. E. Burstal.
18 March 1868.

by a weir which was only a little below the surface of the water. By this process the sewage was deprived of its suspended and of a considerable portion of its dissolved matter; but, as in the last case, it was necessary that the defæcated sewage should be received into a considerable volume of running water, to prevent a secondary putrefactive change. At Hertford the defæcated sewage water is filtered through coarse sand, and it runs a distance of nearly a mile before it enters the river Lea. We remarked that although it left the filter a little turbid from suspended lime, yet it became clear after it had run about a quarter of a mile in the conduit.

In the performance of this process of defæcation we are of opinion from the results obtained at Leicester and Hertford that,—

1st. The proportion of lime should not be less than one ton, and that there should also be used 56 lbs. of chloride of lime per 1,000,000 gallons of sewage.

2d. That the mixture of the sewage with the lime and chloride of lime should be very complete, and that the mixture should be agitated so as to aggregate the suspended matters, and thus assist in the subsequent precipitation of suspended matter.

3d. That the sewage when thus treated with lime should flow along two subsiding tanks in series; the first should be capable of holding at least an hour's flow of sewage, and the second of holding not less than four hours' flow. The tanks should be 4 feet in depth, and the overflow of the defæcated sewage should be by a weir only half an inch below the surface.

4th. That there should be a double set of tanks for alternate working.

5th. That the defæcated water should flow through a shallow open conduit of not less than a quarter of a mile in length before being received into a stream of freely running water of not less than eight or ten times the volume of the defæcated sewage.

With these general remarks we proceed to state what in our opinion should be the standard of purity for the defæcated water.

1st. It should be free from offensive odour.

2d. It should be free from suspended matters, or, in other words, be perfectly clear.

3d. It should not be alkaline to turmeric paper, nor acid to litmus paper.

4th. It should not contain per gallon more than 60 grains of solid matter, dried at 260° of Fahrenheit.

5th. It should not contain more than three-quarters of a grain of organic and ammoniacal nitrogen per gallon.

6th. It should not contain more than two grains of organic carbon per gallon.

7th. It should contain not less than one cubic inch of free oxygen in a gallon.

These particulars of the standard of purity are derived from the practical results obtained in the defæcation of sewage on a large scale, as shown by the analytical table in the Appendix, as well as from the smaller operations of the laboratory.

In conclusion, therefore, we beg leave to state in the reply to the specific questions submitted to us in your reference, that,—

1st. Sewage water can be so purified as to be admissible into the river Thames.

2d. That this purification can be effected by the process of irrigation or of chemical precipitation.

3d. That sewage water so purified ought not to exceed the foregoing standard of impurity.

(Signed) E. Frankland.
Hy. Letheby.
Wm. Odling.

P.S. The conditions under which fluid which has been contaminated with sewage may be admitted into the Thames, as prescribed in the foregoing report, will, I have every reason to believe, preserve the river from being offensive to the inhabitants upon its banks; but, whilst thus far agreeing with my colleagues, I wish it to be distinctly understood that, in my opinion, such fluid can only be safely admissible into the Thames on condition that the water is not afterwards used for domestic purposes. Neither by the processes of purification mentioned above, nor by any others of a practical nature, at present known, can water which has once been contaminated with sewage be, in my opinion, again rendered safe for human use.

(Signed) E. Frankland.

Thames Conservancy Offices,
41, Trinity Square, Tower Hill, E.C.,
March 5, 1868.

Dear Sir,

I have to request that you will inform me whether Dr. Odling and yourself agree with Dr. Frankland in his opinion that the water of the Thames after receiving the sewage water, defæcated in the manner described by you, is unfit for human use.

I am, &c.,
(Signed) E. Burstal,
Secretary.

Dr. H. Letheby,
London Hospital.

17, Sussex Place, Regent's Park, N.W.,
March 6, 1868.

Dear Sir,

In reply to your letter of the 5th instant, I have to state that I cannot at all agree with Dr. Frankland that the water of the Thames, after receiving defæcated sewage water, is unfit for domestic use; for after a large practical acquaintance with the subject as it is observed in the principal streams and rivers of England, I have arrived at a very decided conclusion that sewage when it is mixed with about 20 times its volume of running water, and has flowed a distance of 10 or 12 miles, is absolutely destroyed; the agents of destruction being infusorial animals, aquatic plants and fish, and chemical oxydation.

I have stated this in evidence before Parliamentary Committees and Royal Commissions, and I am satisfied that the opinion is well founded.

I remain, &c.,
(Signed) Hy. Letheby.

Capt. Burstal.

Thames Conservancy,
41, Trinity Square, Tower Hill, E.C.,
March 9, 1868.

Dear Sir,

I have to request that you will inform me whether you agree with the postscript subjoined by Dr. Frankland, to the report made by him, yourself, and Dr. Letheby conjointly, to the effect that the water of the Thames, after

receiving sewage water defæcated in the manner described is unfit for human use.

I am, &c.,

Dr. Odling, (Signed) E. Burstal,
St. Bartholomew's Hospital. Secretary.

Laboratory, St. Bartholomew's Hospital,
Dear Sir, March 9, 1868.

From many considerations, and especially from the fact that the undefæcated sewage, &c., discharged into the Thames, above the source of the present water supply, is not recognizable in the water at present supplied, I am decidedly of opinion that the water of the Thames will not be rendered unfit for human use by receiving sewage water defæcated in the manner described in the joint report of Dr. Frankland, Dr. Letheby, and myself, unless indeed the proportion of such defæcated sewage water should become much larger than there is any reason to anticipate.

I am, &c.,

Capt. Burstal. (Signed) W. Odling.

6854. Have any steps been taken beyond giving notice to those towns?—The time stated in the notices, namely, 13 months, has not yet expired. I am not quite sure when the notice will expire, but I think it will be in May next.

6855. Have any of the towns acted on the notice which you have served, and are they taking any steps about intercepting their sewage?—Yes; I am given to understand that several of the towns have been taking active measures as to what should be done, and some have communicated with us as to the standard of purity of the water which is to be admitted into the river. The conservators have taken no steps to that effect, they only received the report which I have handed in a few days ago. They have considered it desirable that the Royal Commission now sitting should have that report, and they may probably wait until they get the report of the Commission before they take any decisive steps, or give any decided answer to those towns.

6856. From information which you have received, does it appear that the towns as a whole are inclining to the application of the sewage to the land or to deodorizing?—I think they have got both matters in consideration. I have heard that Kingston and Richmond, and that neighbourhood, are taking the thing in hand with the object of sending the sewage away altogether.

Capt. E. Burstal.

18 March 1868.

6857. At the expiration of the 13 months what steps will you take?—I cannot answer that question, because that must remain with the board; but one or two of the towns have applied for an extension of the time, considering that it is impossible to do the work within the time of the notice.

6858. The board have power, under the Act, have they not, to extend the time?—Yes, the board have power to extend the time for three years, that is the maximum.

6859. So as to give them time to carry out any works for the purpose of interception?—Quite so.

6860. Has any difficulty been raised in those towns as to the want of funds to carry out any general system?—They have not told us so. At any rate they have not made a complaint of that description in any communication made to the Conservancy Board.

6861. Has that been so at Reading?—We have had no direct communication from Reading, but there has been a pamphlet printed which shows the steps which have been taken by the Reading local board for the purpose of devising a scheme for deodorizing or getting rid of the sewage.

6862. Does your board intend to act upon the report which you have handed in of those three gentlemen as to the standard?—I cannot quite tell you that, because they have considered it right to send this report to you, and whether they will act upon it immediately or not I cannot tell. If the report of the Royal Commission should come out pretty readily, I think it is most likely that the Conservancy Board will take your report also into consideration along with that. They would consider that the evidence published with your report, and your report together, will enable them to form, perhaps, a better opinion upon the subject than the joint report of those three gentlemen. I merely say that that is their opinion, from what I have heard. There has no positive statement been made at the board as to that matter, but I feel pretty nearly sure that that is the intention of the board.

The witness withdrew.

Richard Meeson, Esq., examined.

R. Meeson, Esq.

6863. (*Chairman.*) Are you an engineer?—No, I am the proprietor of the chalk works at Grays, in which some very large springs are situated. I have worked them myself for a great many years. The water springs are situated in the chalk pits at Grays, in Essex, about a mile distant from the Thames. When undisturbed they rise to a height varying from about four feet to eight feet below Trinity high-water mark. The chalk had been worked out to the level of the springs over an area of about 60 acres when attempts to go deeper and get more chalk led to the discovery of a most abundant supply of pure water in about the year 1852. We employed five pumps to begin with; four 9-inch lifting and one 11-inch centrifugal, driven by two 8-horse and one 6-horse engines. The depth of water which passed over the gauge, which was 3 feet 8 inches wide there, was $5\frac{1}{4}$ inches, so that the quantity then obtained every 24 hours exceeded 2,100,000 gallons, besides that used on the works. This quantity was delivered daily, the engines being worked day and night, ceasing for only a few hours between Saturday evening and Sunday morning. During the week the water was lowered about 12 feet, and it then became possible to excavate the chalk to that additional depth over a small space; but when the engines ceased working the water speedily rose to its former height, and it occupied an entire day and night so to reduce the water as that work might be resumed; and throughout the entire remainder of the week the springs yielded the supply I have mentioned, which was all that the pumps then in use were capable of delivering. When a space of about 30 yards square has been excavated to a depth of about 12 feet, the pumps are overpowered by the increased pressure of water, and we have found that it would answer to begin in a fresh place 3 or 4 feet away, and by abandoning the first place, which still remains full of water, we have gone and pumped out of the other without disturbing the level of the first spring. We have had four or five of those pits sunk about 30 yards square, one after the other, leaving about 4 feet of chalk between them. These operations have been carried on now for many years, yet notwithstanding so large a quantity has been pumped daily into the Thames, no perceptible alteration has taken place in either the quantity or quality of the water.

6864. Is the water used, or is it pumped into the Thames simply to get rid of it?—It is now used. We supply Brentwood and Romford, and all the places between there. We have not got a demand for above 1,000,000 gallons daily now, although we supply the barracks at Warley. That is all pumped out of one small well about 6 feet in diameter, without interfering with the other water at all.

6865. I understand you to state that you could raise 2,100,000 gallons per diem?—We did do so; but now we are prepared to take contracts for 10,000,000 gallons a day at least.

6866. When you were raising 2,100,000 gallons you were obliged to rest, and you depressed your water level 12 feet?—Yes.

6867. Had you to rest 24 hours in order to regain

R. Meeson, Esq.

18 March 1868.

the level?—No. When it was down that depth of 12 feet we could not reduce it that depth in 24 hours.

6868. But had you to rest 24 hours before you could keep it at the original height?—No, we only rested for a short time between Saturday and Sunday morning; the water kept at its original height.

6869. (*Mr. Prestwich.*) What is the greatest quantity that you have obtained from those springs?—The greatest quantity that we ever got rid of was 7,000,000 gallons a day, and that went on for about six months.

6870. Are we to understand that the pumping continued day and night for a month, and yielded that quantity every 24 hours?—Yes.

6871. Did that lower the water?—Not permanently; it was up again in a very short time.

6872. To what depth did the level fall during the time that that quantity was being pumped?—About 18 feet at the lowest point of all.

6873. When it was sunk to a level of 18 feet how low was it below the level of the Thames?—At the level of low-water mark. The level gauge stands there now.

6874. Have you any reason to suppose that when it fell so low there was any introduction of water from the Thames? Did the analysis of the water at that time show any variation in the quality of the water?—I have no reason to think so, because chalk water will not percolate at right angles to the fissures. Along the fissures the water will flow freely, but across them it will not.

6875. Was any analysis of the water made at that time?—Yes.

6876. Did the quality of the water at that time show any difference compared to what it was at other times?—We had three analysis, made at different times, and there was no alteration whatever in the qualities of the water.

6877. Have you the analysis of this water?—Yes.

6878. By whom was the analysis performed?—By Mr. Dugald Campbell and by Dr. Dundas Thompson, and I have also another analysis made for the West Ham Board of Health by Dr. Voelker, who did not know where the water came from.

6879. (*Chairman.*) Will you put in those analyses?—Yes.

The same were delivered in, and are as follows:

REPORT on the CHEMICAL EXAMINATION of a SPECIMEN of the "GRAYS THURROCK WATER," UNFILTERED, by MR. DUGALD CAMPBELL, F.C.S., Analytical Chemist to the Brompton Hospital, &c.

The total solid contents per imperial gallon of 70,000 grains at 60 degrees Fahrenheit were found to be 26·88 grains, consisting of—

Mineral matter	25·36 grains.
Volatilized matter	1·52 ,,
	26·88 ,,

The mineral matter, on examination, was found of the following composition:—

Silica	0·96 grains.
Carbonate of lime	15·33 ,,
Sulphate of lime	1·13 ,,
Nitrate of lime	1·67 ,,
Carbonate of magnesia	1·47 ,,
Chloride of sodium	2·57 ,,
Carbonate of soda	0·68 ,,
Sulphate of potash	1·55 ,,
	25·36 ,,

Degrees of hardness by soap test, 16·6.

The volatilized matter does not blacken in the process of expelling it, consequently it does not exhibit the presence of any animal or vegetable substances.

When the water is boiled for a short time its hardness is very much decreased, and I found it then to be 5·85 degrees instead of 16·6.

ANALYSIS WATER from the SPRINGS AT GRAYS, ESSEX, by ROBERT DUNDAS THOMSON, M.D., F.R.SS. L. & E.

When subjected to quantitative analysis it yielded the following composition, per imperial gallon, in grains:—

Volatile matter	1·60
Silica	1·60
Sulphate of potash	1·30
Sulphate of lime	·95
Carbonate of magnesia	·96
Carbonate of lime	16·13
Carbonate of Soda	·30
Nitrate of lime	1·23
Chloride of sodium	2·33
	26·40 grns. per gal.

The chalk present in solution gives the water 16·13 degrees of hardness, which could be removed by the liming process of Dr. Clark.

ANALYSIS by Dr. AUGUSTUS VOELCKER.

An imperial gallon on evaporation left dry residue (dried at 260° F.).

	Grays. No. 1.	E.L.W.W. No. 2.	No. 3 West Ham Distillery Well.
Solid residue per gallon	27·05 grs.	23·80 grs.	*23·50 grs.

* 1·15 grains of this residue was finely suspended matter.

The analysis of the solid matters in the three samples of water yielded:

——	No. 1 Grays.	No. 2 E. L.W.W.	No. 3 Well.
Loss on gentle heat	1·29	1·80	·85
Oxides of iron and alumina, and traces of phosphorine acid	traces	traces	·55 principally oxide of iron
Lime	10·36	9·12	4·59
Magnesia	·66	·83	3·02
Chlorine	2·21	1·36	2·31
Sulphuric acid	1·53	1·85	2·40
Nitric acid	1·73	·42	·02
Soluble silica	1·05	·50	·45
Alkalies and carbonic acid (determined by difference)	8·22	7·92	9·31
	27·05	23·80	23·50grs.
Oxidisable organic matter per gallon	·416	·71	·64grs.
Hardness, according to Dr. Clarke's scale—			
Before boiling	18⅔°	16°	15°
After boiling	6½°	4⅘°	9°

Uniting nitric and sulphuric acid with lime, and the rest of the lime and the magnesia with carbonic acid, and assuming chlorine to exist altogether as chloride of sodium, the three waters may be represented to contain:—

——	Grays.	E.L.W.W.	Well.
Oxide of iron and aluminum	traces	traces	traces
Nitrate of lime	2·44	·64	·03
Sulphate of lime	2·60	3·14	4·08
Carbonate of lime	15·32	13·98	5·19
Carbonate of magnesia	1·38	1·66	6·04
Chloride of sodium	3·64	2·24	3·87
Soluble silica	1·05	·50	·45
Oxidisable organic matter	·41	·71	·64
Alkaline carbonites and loss not determined	·21	·93	3·20
	27·15	23·80	23·50

Analytical Laboratory,
11, Salisbury Square,
Fleet Street, E.C., Dec. 10, 1866.

AUGUSTUS VOELKER.

6880. (*Mr. Prestwich.*) Have you any analysis of this water made by Dr. Frankland?—No, only by Dr. Thompson, his predecessor.

6881. I believe that Dr. Frankland's analysis shows some difference with those two analyses by Mr. Camp-

bell and Dr. Thompson?—I have never seen any analysis by him.

6882. (*Chairman.*) What is the degree of hardness of your water?—16·13.

6883. Have you applied Dr. Clark's system of softening to your water?—Yes.

6884. With what result?—It is reduced to 4·8, but it is not a permanently hard water, when boiled it is quite soft enough for anything.

6885. What do you reduce it to by boiling?—5·8. It is very much approved of for locomotives. The Great Eastern Railway Company take it at Brentwood for that purpose.

6886. (*Mr. Prestwich.*) Is the water clear at all times?—Always perfectly clear.

6887. (*Chairman.*) Are you permanently using Clark's process?—No; it is preferred without I should say, certainly for drinking it is pleasanter without the softening process, because it contains a very considerable quantity of carbonic acid gas.

The witness subsequently sent in the following letter:—

Ship "Lincolnshire," E. I. Docks,
October 17th, 1861.

I certify that the water contained in a cask marked K was taken out in the above ship from Grays, on 21st March 1861, in jars; that it was shifted into the cask on the line during our voyage to Melbourne, and is the same water as left Grays; that I tasted the water several times on the voyage, and always found it in good condition, and better water than I have before taken to sea.

G. E. Bulmer, Chief Officer.

The witness withdrew.

John Bravender, Esq., F.G.S., examined.

6888. (*Chairman.*) You are a land agent and surveyor residing at Cirencester, are you not?—I am.

6889. Has your attention been directed to the subject of the supply of towns with water?—It has.

6890. And to the capacity of that district to yield a supply for the metropolis?—Yes, it has, and for other purposes; for the local towns in our own neighbourhood.

6891. Can you state to the Commission the result of your investigations?—I believe the Commission have before them a paper of mine, and I wish to show the steps that I have taken which bring me to the conclusions which are therein stated.

6892. You reside, do you not, near to where the last witness has given evidence about?—Yes, close by him. I live in the town, and he lives about a mile from it.

6893. Did you hear his evidence?—Yes.

6894. Do you concur generally in it?—Not altogether. I differ from him in one respect. I do not think it necessary to take the water above the mills. I should recommend you to take it below the mills, before it arrives at the Thames. There are 10 or 11 mills on the river Churn, which flows through the town of Cirencester, and there are 10 or 12 mills on the river Coln, which runs through Bibury and joins the Thames between Fairford and Lechlade, and those millowners which he alluded to most likely would be the parties to form a very serious opposition to your taking the water of those rivers, if it were taken from the rivers above the mills.

6895. Do you agree with him as to the yield of the district generally, apart from the question of interference with the rights of the millowners?—Yes. From my own observation my idea is, that 28 inches of rainfall might be taken as the general average of the whole of what I call the district of the Upper Thames, that is above Oxford—he says 30. I have observed it myself for a long time, though I have not a gauge, and I believe that he has given a greater average than was shown by the gauge at the Royal A. College, some time since.

6896. How could you observe without the means of gauging?—From taking notice of gauges kept by other people, the register kept at the Royal A. College, for instance, to which I had access. I have not brought a register with me of observations, but speaking from memory I believe that he has given a higher result than has been taken elsewhere. I think the Cotswold Hills are situate 300 or 400 feet above his house, and a great deal of the supply from the Coln, the Churn, the Windrush, and the Evenlode, comes from hills much higher situated than where his rain-gauge is; I believe you will find that the higher you ascend the less the rain-gauge will show, and the lower you descend to the level of the sea the greater the quantity the rain-gauge will show.

6897. That will depend upon the aspect, will it not?—Perhaps it might to some extent, and particularly where the country is covered with woods. I only give an opinion; I know that some of his observations from his own gauge do not exceed 28 inches. I have written a paper which I believe has been placed before the Commission through the Earl of St. Germans.* I have been very much interested in this matter, and I wrote that paper and handed it to him, and I think he caused it to be placed before this Commission. My great object would be to show you the mode in which I have treated the subject, to satisfy you that there is something reasonable in the propositions which I have made in that paper.

6898. Does this paper contain additional information which you desire to lay before this Commission?—Yes; I have some additional matters to lay before you. I rely principally upon the ordnance map. I have examined the watersheds personally on the ground. I know almost every inch of the ground between Gloucester and Oxford, having for some purpose or other been called into almost every field in the upper vale of the Thames. I have been engaged for the poor-rate valuation and for other purposes to a very large extent, and you will find I have marked upon the ordnance geological map the districts which I have named in my paper.

6899. Can you state the result of your rainfall of 28 inches?—Taking the evaporation at 10 inches, and the absorption and waste at 9 inches, we have 9 inches of available water left, and 9 inches deep on a square mile will give 774,400 cubic yards per square mile, and this multiplied by 875 will give 677,600,000 cubic yards for the available water of the upper Thames watershed, or 1,856,438 yards, equal to 313,523,912 gallons per day. I should take the water above the junction with the Thames, after it has served all the purposes of the land, and after it has turned all the mills that are upon those streams. But it would be extremely desirable not to take it until an Act of Parliament has been passed to compel the small towns which are situate upon those rivers to keep their sewage out of them, and dispose of it as they are now obliged to do upon the line of the Thames. Our town of Cirencester is more than three miles from the Thames, and therefore we are not compelled to keep the sewage out of the Churn, but we are contemplating doing so; it is impossible to go on without. I think Mr. Brown is in error about the gravel bed at Cirencester. The gravel bed at Cirencester is entirely local, it has been brought down by denudation and there deposited upon the great oolite with the fuller's earth beneath. It is true that the Forest marble once covered the place, but it has been broken up at the time of the denudation and become mixed with this gravel, the clay forming a thin bed on the great oolite, and the gravel 10 or 12 feet thick above it. This enables the inhabitants to make wells about eight or ten feet deep, and they get a considerable quantity of water except in extremely dry seasons. Occasionally parties have found it impossible to get water in dry seasons from those wells, and the necessity has arisen for people to sink their wells deeper, and I and some others have gone

* See Appendix II.

J. Bravender, Esq., F.G.S.

18 March 1868.

deeper upon premises which belong to us in Cirencester. I know that the well on my premises is nearly 30 feet deep, and that it goes into the fuller's earth, and it is not at all dependent upon this gravel bed and has no connection with it whatever. I know that the well in the marketplace at Cirencester is from 26 to 30 feet deep, and I know that it pierces into the fuller's earth, and when those shallow wells become deficient a great many people make use of that well, and it supplies a very large quantity of water; in fact the supply from the fuller's earth is almost inexhaustible. The engine at the Thames head in the driest summer has never been able to exhaust the well there. The well is 64 feet deep, and Mr. Brown stated correctly that for months together the engine throws up more than 3,000,000 gallons into the summit level of the Thames and Severn canal every day. I visited this engine on the 6th of March 1864; it had been going for two years and had not been suspended any longer than for six hours during the whole of that period. There were then 26 feet of water in the well, and the engine was making no impression upon it. I visited it subsequently in a very dry season indeed, at the end of the same year, and I found that there was 9 feet of water in the well, and the engine was making no kind of impression upon it, although the country was dry and scarcely any water in any of the rivers or brooks.

6900. (*Col. Harness.*) You were only taking 3,000,000 gallons?—They were only taking 3,000,000 gallons.

6901. (*Chairman.*) And the water level was depressed 17 feet?—Yes, it was depressed 17 feet, and the engine could not depress it any lower. I will put before the Commission a plan showing the situation of the Thames head engine, the shaft and the well. It has marked upon it the depths pierced into the fuller's earth (*handing a plan to the Commissioners*). The dip is south-east, and you will observe that the Boxwell spring is situated in the parish of South Cerney, $4\frac{3}{4}$ miles south-east of the Thames head engine, at which point there is a considerable geological fault, which throws up an immense quantity of water from the fuller's earth. Two or three years ago the inhabitants of Cheltenham brought in a bill in order to obtain water for the supply of that town from this spring. I measured the spring on three or four occasions. It does not vary like some other springs; it runs not altogether summer and winter alike, but varies about 500,000 gallons between winter and summer. It gave out on the 6th of March 1864 1,500,000 gallons in round numbers per diem, and when I measured it, on the 8th of October in the same year, it was discharging 1,100,000 gallons, and that was the only water at that period which ran down the Thames. The whole of the water in the Thames besides this had become completely exhausted. In addition to my paper I have some observations which it may be proper to mention here. In the summer of 1864 the Earl of St. Germans decided on deepening and improving the Thames below and adjoining his property, with the view of obtaining a better outfall for the drainage which had been executed under my superintendence on the Down Ampney estate. This estate is situated near Cricklade, at the top of the upper Thames, and is bounded by the Thames from the town of Cricklade to near Castle Eaton, in distance more than three miles. In August of the year 1864 we found the water sufficiently low to enable us to commence the works, and on the 24th of that month we succeeded in confining nearly all the water descending the river into a definite space of 12 feet in width. I carefully ascertained the velocity and depth and found that 13,000,000 gallons were passing in 24 hours. This observation was made towards the upper part of Marston Meadow, about half a mile to three-quarters of a mile above Castle Eaton bridge. On the 13th of September the water passing down the river was confined to a width of $4\frac{1}{2}$ feet in another part of the river further up. The depth and velocity were carefully taken, and I found that about 7,000,000 gallons were descending in the 24 hours, the river having decreased nearly half in volume in 20 days. On the 8th of October the water passing down the river was confined to a width of 3 feet a little below the bridge at Water Eaton. I again carefully ascertained the depth and velocity, and found that rather more than 1,000,000 gallons were descending in the 24 hours. In the morning of this day I had ascertained that no water was passing down the Thames at the bridge at Cricklade (that was about a mile above); there was no water in the river there except in the hollows in the bed of the river in a few places. I examined the Churn, which flows into the Thames near Cricklade, and found it completely dry at South Cerney; and on descending the stream to where the water from Boxwell spring joins the Churn I observed a considerable quantity of water flowing into the Churn from Boxwell spring. On visiting Boxwell spring, about a quarter of a mile up the brook from this junction, I found it discharging about the usual quantity. I had some time before ascertained the flow of this spring and did so at this time, and found the discharge about 1,100,000 gallons in 24 hours. The fact is that the water passing Water Eaton was from the Boxwell Spring, and in passing over about three miles of porous gravel and somewhat peaty soil there was a loss of 100,000 gallons per day at that time. This loss would eventually find its way into the Thames lower down the vale. It may be observed that from the middle of August to the middle of October there was scarcely any rain fell, and that which did fall was absorbed immediately, and made not the least difference to the water in the Thames. Our observations extended over 45 days, from the 24th of August to the 8th of October, and during this period the entire supply of the Thames above Water Eaton ceased, except what was supplied by Boxwell spring. I might say that I have not only gauged Boxwell spring but I have taken the temperature of it, and I find that the water discharged from it is about two degrees higher in heat than the water in the canal not 10 yards from it, and in winter the frost does not freeze over the spring nor the brook for 200 yards below its source so soon as it freezes over in other places, and I have seen steam rise from the water in the winter time when it has issued from the spring. I called Dr. Voelcker's attention to this when he was at the R. A. College. The reason is this, that the water in the summer time when it is warm weather falls upon a large area of the upper oolite in a very warm state; it descends rapidly through the porous rock and comes on to the surface of the fuller's earth, and descending gradually for several months it issues from this spring at a higher temperature than the water on the surface, because the winter has come on the surface but has no effect below, and that is the cause of the difference in the temperature. Having alluded to the great loss in the Churn by passing over the porous rock of the under oolite, I may be excused in quoting a table of the results obtained in 1859, and I do so with the greater confidence because those results were obtained from a series of observations made by myself under the direction of Mr. Simpson, extending over a period of six weeks. At that time the millers complained very seriously of the loss of water from the Churn. I was concerned for two or three landowners and I told them what I thought was the cause; they hesitated in believing what I had to say. They thought that Mr. Hutchinson and Mr. Elwes, whose property lies upon the lias, were the parties who caused the loss of water, because the one had made a fish-pond and some ornamental water, and another was driving a saw-mill and diverting the water. They thought by those works they were deprived of the water. I believed that they were not, and in consequence of our difference of opinion I recommended them to call in some practical engineer, and Mr. Simpson was called in. When he sent down his assistant I went over the river with him and pointed out what I thought

was the cause, and after a minute inspection we decided upon placing on the river some sizes, and he left me and my assistants to measure the water for six weeks. We took it very accurately and made a return at the end of six weeks. He then made his calculations, and this is the result. I have with me a plan showing where all the sizes were put in and the discharge of each spring. The Seven Springs is a place about four miles from Cheltenham upon the road to Cirencester, and is the head of the river Churn. There the water is thrown out by the lias and it is the furthest tributary of the Thames. At the Seven Springs the flow was 11 cubic feet per minute. At a quarter of a mile below the springs the flow was 31 cubic feet per minute; at three-quarters of a mile below it was 61 feet; at one mile below it was 73 feet; at two miles below it was 105 feet; at $2\frac{1}{2}$ miles below it was 165 feet; at $4\frac{3}{4}$ miles below it was 312 feet; and at $5\frac{1}{2}$ miles below, estimated at the maximum, it was 320 feet. Then we got off the lias on to the rubble beds of the under oolite which were absorbing a large quantity of water, which I had pointed out before the observations commenced; but at this point the volume of the river instead of increasing began to diminish, for at $6\frac{1}{2}$ miles below the spring the flow had decreased to 290 cubic feet per minute; at 7 miles below it had decreased to 235 feet; at $7\frac{3}{8}$ miles to 179 feet; at $8\frac{1}{8}$ miles to 113 feet; at $8\frac{7}{8}$ miles to 45 feet; at $9\frac{3}{4}$ miles to 33 feet; and at $12\frac{1}{2}$ miles below it had decreased to 30 cubic feet per minute, almost absorbing the whole of the springs above. The loss of water in descending the Coln is much greater than the loss to the Churn, and I have no hesitation in stating that if this river (the Coln) was thoroughly puddled, as Mr. Simpson recommended, in 1859, in the case of the Churn, the Syreford spring, a spring which discharges 3,000,000 gallons in the course of 24 hours, and sometimes more, might be sent down to Cheltenham, and the abstraction of the water would not be felt at Foss Bridge, which is about four miles from Withington, where the lias terminates. Between Foss Bridge and Withington there is oolite in the bed of the brook which absorbs an enormous quantity of water. The inhabitants of Cheltenham tried to get this Syreford spring diverted into Cheltenham, but Lord Eldon and some others who had some mills on the river opposed it, and the inhabitants did not succeed. Mr. Simpson was engaged then for Lord Eldon, but it did not suggest itself to him that if this river were puddled they might safely take the whole 3,000,000 gallons into Cheltenham; it would have gone down to Cheltenham by the mere force of gravity, and might have been carried to the top of the highest building in the place. There has been a doubt as to the source of the spring called the Thames head, which is not far from the engine which I have shown upon the plan. It is an intermittent spring, that is, it only discharges at certain seasons when there is a large body of water descending the plane of the stratification of the fuller's earth; when it rises higher in the bed of oolite than the surface, it discharges; but whenever the water falls below that point the spring ceases to flow. The Rev. Mr. Clutterbuck appears to think the "Thames head" is derived from the Oxford clay, and I have for many years considered the watershed of the Forest marble totally inadequate for the supply of so large a quantity of water as is pumped up by the Thames head engine, and that the source of this spring must be the fuller's earth; and I believe Mr. Taunton agrees with me. Many persons in the neighbourhood have heard of a spring called "Winterwell;" this spring like that of the Thames head is an intermittent spring, that is, only sending out water in very wet seasons, and in dry seasons ceasing to flow altogether. Some years ago I had occasion to deepen a well in Winterwell bottom, not far below the spring just mentioned; this well was only 10 feet deep and had become dry; we sunk it 6 feet deeper and obtained an abundance of water, and have had plenty ever since. The summer was a dry one; all the materials which were brought to the surface I recognized as the shale and rough ragstone from the top of the fuller's earth. I was acquainted with the material, having previously sunk several wells into it, and always obtained an abundance of water. One well at the White Way, near Cirencester, is 65 feet deep, another at the Bowling Green farm, 30 feet deep, and my own well in Thomas Street, Cirencester, 27 ft. deep, and I succeeded one dry summer afterwards in getting it 3 feet deeper into the fuller's earth. The well in the market place at Cirencester is 26 feet deep, and this well has never been known to be entirely dry. It will be remembered that last autumn we had some wet weather, and being desirous of fixing the source of these intermittent springs, I invited Professor Morris, who was then lecturing at the Royal Agricultural College, to go with me to see those springs. We visited Winterwell spring first, and found it discharging an enormous quantity of water. This was on a Friday, and the occupier of the land informed us that "Winterwell broke out middle day on the previous Sunday." We left Winterwell and drove directly to the Thames head spring, which is situate on the south side of the canal close to Trewsbury quarry about half a mile west of the engine (which is mentioned on the geological map), where a quarryman lives. We inquired of him when Thames head broke out, and were informed that it was on the previous Sunday, showing as I think that the two springs have the same source, and continue to flow only while the rock above the fuller's earth is saturated up to a line above the surface. The surface at Winterwell spring is 20 feet above the fuller's earth, and that of the Thames head a little more. I think Mr. Taunton says 29 feet, but I have been unable to ascertain this myself. Those remarks on springs are incidentally introduced, but at a future period I may return to this subject, and the springs of the upper Thames watershed and their volume will afford abundant matter for a thorough investigation. Those are the remarks which I wish to add to the paper which I have already sent to the Commission. I have some observations of the watershed giving my opinion as to which are the beds which absorb water and which are the beds which do not absorb water or very little.

6902. All we desire is to ascertain the amount of rainfall, and the area and probable quantity flowing off into rivers which would be available for a water supply?—Then I will put it in.

The same was delivered in, and is as follows:—

Remarks on the Geological Strata of the Upper Thames.

In the Thames watershed we have the lias, under oolite, fuller's earth, upper oolite, forest marble, cornbrash, kelloway, and Oxford clay, on the north of the Thames.

The Oxford clay, coral rag, coralline oolite, Kimmeridge clay, Portland oolite, lower greensand, gault, upper greensand, and the chalk to the summit of the chalk hills, on the south side of the Thames.

The following are porous, and absorb a large quantity of the rain as it falls.

Under oolite.	Coralline oolite.
Great oolite.	Portland rock and sands.
Cornbrash.	Greensand.

Sandy beds of Forest marble and the chalk.

A great portion of the rain runs off the following strata as it falls:—

Lias - - -	A great portion runs off, except where covered with diluvium.
Fuller's earth - - -	Nearly all runs off; area very small.
Forest marble - -	Part absorbed by sand beds, and about one-fourth of the remainder runs off.
Oxford clay and kelloway.	Part runs off and part is absorbed by the surface gravel; but the whole, or nearly the whole, of the water of the Oxford clay reaches the Thames.

J. Bravender, Esq., F.G.S.

18 March 1868.

Kimmeridge clay	- A considerable portion runs off.
Gault - -	- Greater portion runs off, but partly absorbed again by the lower greensand.

At the head of the Churn, Coln, Windrush, and Evenlode, the under oolite has been cut through on the south and south-east side by denudation, which is the means of bringing to the surface a large quantity of the water which falls on the under oolite above. Without this denudation the vale of the Thames could not receive any of the rainfall on the upper portions of the under oolite; nor could any of the rainfall on the fuller's earth reach the Thames but for this denudation, except what may be thrown out by means of faults. Like the water on the lias it would all quietly descend the slope of stratification and pass many feet under the Thames.

The fuller's earth is a thick bed of very retentive clay, and no water passes through it. It retains on its surface, beneath the upper oolite, an enormous quantity of water.

A very large portion of the rainfall of the great oolite and forest marble, particularly that which falls on the sandy beds, descends through those formations to the fuller's earth below, and thus accumulates the enormous quantity there found, part of which, fortunately for the country at the head of the vale of the Thames, is brought to the surface by means of geological faults, which form large and never-ceasing springs. The principal springs are—

Boxwell spring,
Ewen spring,
Ampney spring,
Bibury spring,
Ablington spring,
Winson spring,

and others. Also three intermittent springs, called "Winterwell" and "Thames head," and one opposite Trewsbury quarry also called "Thames head."

The fuller's earth is the source from which the "Thames head" engine supplies the Thames and Severn Canal on its summit level with most of the water. There is a conduit which conveys a portion from the forest marble into the well at the engine, but this forms but a small portion of the supply. The engine pumps up three millions of gallons in 24 hours for months together in dry seasons without ever drying up the source, and I have no doubt of the capability of the fuller's earth at the head of the Thames to supply water for several more engines at the same rate, which would be sufficient for half a million of the inhabitants of London.

As the water on the surface of the fuller's earth in the neighbourhood of the "Thames head" could never reach the surface of the ground in summer time, no one could complain of the loss by pumping; but, on the contrary, an abundance would be brought to the surface, which would not reach it in that neighbourhood, and probably not in England, without pumping.

Complaint might be made in consequence of taking the water from off the forest marble, but this may be entirely avoided.

The whole of the rainfall of the Oxford clay and kelloway would find its way into the Thames between the western summit and Oxford. There are few, if any, springs, properly so called, in the Oxford clay. A great portion of it is covered with gravel and alluvial soil some feet thick, and the rain rapidly sinks through the soil and gravel down to the impervious clay, and thence escapes into the ditches and brooks, and thence into the Thames, without appearing on the surface in large springs. The body of gravel is not sufficient to retain it for any length of time, which is a necessity for a spring. A spring thus produced ceases soon after the commencement of dry weather.

With regard to the area of what I have called the Upper Thames, extending from Oxford up to the higher point of the watershed, it contains 875 square miles, and that watershed has at least 28 inches of rainfall; Mr. Brown at one end of it tells you that it is 30 inches; I have no doubt whatever that 28 is a reasonable estimate, and that you might take away one-third of that for evaporation and one-third for absorption and waste, which would leave 9⅓ inches of water available, but in my calculations I have only taken 9 inches.

6903. You state in that paper which you have furnished to the Commission, "The rainfall over this "875 square miles may be taken at 28 inches per "annum, from which 12 inches should be deducted "for evaporation"?—Yes, but when I want to make any calculations as to the available water I reduce it to 9 inches; there is the absorption beyond that, I do not found any calculation upon that, you will find that I make the calculation on 9 inches.

6904. (*Mr. Prestwich.*) Have you any other estimate of the rainfall besides that given by Mr. Brown?—No, I have not. I had a copy from the register taken for some time at the R. A. College, but I have mislaid it.

6905. This rain gauge of Mr. Brown I presume has been carefully kept?—Yes, during a period of 20 years, I believe. He is a very careful man, and he pays every attention to it. I have stated in my paper that in order to take the water and make reservoirs in certain places, there was an abundant fall between those places and Paddington; and to prove to you that I have some ground for making that calculation I will show the Commission an outline section of the Great Western Railway from Cheltenham to Paddington (*producing a section and explaining it to the Commission. See Appendix X*). The station at Swindon, where there might be a reservoir placed, is 250 feet above the level of Paddington. I propose to have reservoirs made at the mouths of the Coln, Windrush, and Ock, and that the water should be conducted down by the side of the Thames from the Coln to a place called Langley weir, and thence in a straight line, which would be nine miles across the country, to Didcot station. Then I propose that the water should be taken alongside the Great Western Railway to Paddington. This section which I have been showing the Commission is the original section which was handed over to me when I was engaged to purchase the land for the railway from Swindon to Cheltenham, and it exhibits the level of the rails, and I have taken the fall from that section. There is a fall of 1 in 1,320, or 4 feet per mile, between Swindon and Paddington. I have also a geological section of the line from the Sapperton tunnel. (*The witness described the construction of the tunnel and the geological formation of the ground.*) I have also brought with me a copy of the plan which was made in the time of Mr. Simpson, and an analysis which was sent me by Professor Church of the water from the Boxwell spring, and also an analysis of the water of the Seven Springs, which is said to be the head of the Thames, if they should be of any use to the Commission.

Witness handed in the following analysis of water, by A. Church, Esq., Professor of Chemistry at the Royal Agricultural College, Cirencester:

Boxwell Spring, taken 4th March 1868.
Temperature of water, 49° Fahr.

	Grains.
Total solid contents per imperial gallon - -	26·30
Loss on ignition, commonly called "Organic matter"	1·28
Carbonate of lime - - - - -	18·30

Seven Springs, taken Sept. 1, 1866.

Solid contents - - - - -	18·33
Lost on ignition - - - - -	0·83
Carbonate of lime - - - - -	11·83

6906. What is the sum total of those various springs which you have described; you have described Boxwell spring which gives a yield of above 1,000,000 gallons a day, and you say that the pump at the Thames head delivers 3,000,000 gallons a day; can you enumerate the other springs?—There is a spring at Ewen which gives the same as Boxwell spring, or a little more than 1,000,000 gallons. There is Ampney spring at Ampney Crucis, two miles east of Cirencester, which is thrown out from the fuller's earth by a fault, and which gives out an enormous quantity. It is very difficult to measure it because it comes out at two or three different places, but it all passes at one place near to a mill, and I gauged it there at 4,000,000 gallons in 24 hours, and in summer time about half that quantity.* Then there is

* The following was subsequently communicated by the witness:—"This was only *one* portion of the spring. I find in April /66 I "measured the entire flow near the mill and found it to be con-"siderably more than 20,000,000 gallons in the day; and yesterday I "visited this spring and carefully measured the flow of water, and "find that upwards of 30,000,000 gallons were passing the bridge near "the mill. I also visited Bibury spring and found it discharging "rather more than the one at Ampney Crucis."

a spring at Bibury which comes from the same source and which gives out about the same quantity. There is a spring about a mile above that at Ablington which I have also gauged, and that gives out quite enough to turn a mill; the discharge is more than 2,000,000 gallons. Then there is a spring above Winson from the same source which gives out about a million and a half. The Bibury, Ablington, and Winson springs are on the Coln, the Ampney spring is between the Churn and the Coln, the Ewen spring falls into the Thames at Ashton Keynes and does not get into the Churn.

6907. What are the limits of height above the sea within which those springs occur?—They are all about the same level as Cirencester, or a little higher, from 300 to 380 feet above the sea.

6908. Then it would appear that the sum total of those springs yields a larger quantity of water than you have stated to pass down the Thames near Cricklade?—Yes; the Coln comes into the Thames near Lechlade, which is a good way down the river.

6909. Did you not express an opinion that if water were taken from that district it might be desirable to take it at or near Cricklade?—Yes, about a mile and a half nearer to Cirencester than Cricklade. This would be from Boxwell spring, from Ewen, and from the Thames head.

6910. Has not your own evidence shown, and do not the observations which you have just made lead to the conclusion, that you would get more water by intercepting the water within a short distance from the springs themselves, because you have shown that many of those springs, after flowing over the porous strata of the oolites, lose a certain quantity of their water?—Yes, that is so, but in such case I contemplate the puddling of the under oolite. Then you might take the whole of that water which is saved by the puddling, and they would not feel it at all, even if you took it above the mills. The saving by puddling would be 3 millions of gallons per day. *J. Bravender, Esq.* 18 March 1868.

6911. Are you at all acquainted with the springs on the other portion of the watershed of the upper part of the Thames, such as those at the foot of the chalk downs?—Yes, I know some of them, they are by no means so strong and so large as ours. There is a spring up near Burderop which feeds the Swindon reservoir which supplies the canal. It is at the head of the Cole, which joins the Thames near Lechlade and passes Coleshill, the residence of Lord Radnor.

6912. Are you acquainted with any large springs in that district?—No, they are all of minor character.

6913. Has not the town of Swindon itself experienced some difficulty in getting a supply of water?—Yes, but it is isolated, it is situated on a hill above the level of the land around it. The town is upon the Portland oolite, and the reservoir is upon the clay beds south of the town. The reservoir is in the hands of a canal company. The town of Swindon is 100 feet above the railway station.

6914. Are there any springs near Ashbury and Little Hinton?—Yes, there are some springs up there, but they are not anything so powerful as ours.

6915. Have you had any opportunity of gauging the Thames lower down than Cricklade?—Not lower down than Castle Eaton.

The witness withdrew.

Adjourned to to-morrow, at 12 o'clock.

Thursday, 19th March 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.
Colonel HARNESS, C.B.
THOMAS ELLIOT HARRISON, Esq.
JOSEPH PRESTWICH, Esq.

RICHARD HASSARD, Esq., further examined. *R. Hassard, Esq.* 19 March 1868.

6916. (*Chairman.*) The Commission have received your letter written on your own behalf and on behalf of Mr. Hemans, pointing out certain evidence of Mr. Bateman's touching your own scheme, and expressing a wish to offer some explanation. It is desirable, of course, that you should confine as much as possible your evidence to those points which are in dispute. We do not want unnecessarily to limit you, but at the same time there are points which you have before touched upon in Mr. Bateman's scheme which you need not now revive. You will perhaps limit your remarks as much as possible to that which you have stated in your letter. Your first point, I see, is as to the provincial towns being at present amply supplied with water; what remarks have you to make upon that?—If you will allow me, before giving any further evidence I wish to make one or two remarks. I wish as much as possible not to take up the time of the Commission by going into any evidence which we have already given you, or by the repetition of evidence upon evidence. I presume that all the advantages which are claimed for the Welsh scheme as regards the benefits to be derived from soft water, constant supply, high service, and purity of water generally, will be conceded to our project; that all those advantages which apply to the one scheme apply equally to the other, and probably to ours in a greater degree on account of the greater purity of the water. But as regards the remark which Mr. Bateman has made upon the estimates of the lake project, and as regards the voluminous and tabulated statements that he put in of comparative estimates between the Welsh project and our project, as I only received the printed copy of his evidence yesterday at 5 o'clock in the afternoon, owing to the time occupied in getting it printed, I must crave the indulgence of the Commission to allow me to go into that part of the subject upon another occasion. I have not had time to analyse the evidence, and as Mr. Bateman has had several months to investigate the question and to prepare his statement, it is scarcely possible for me to reply to him in the few hours' notice which I have had. I shall take but very little time on a future occasion if you will allow me to go into it then.

6917. There are other points, I presume, which you can deal with to-day?—Yes, I am quite prepared with the other matters referred to in my letter, and I should think an hour on a subsequent day would be the outside that I should occupy the time of the Commission.

6918. (*Mr. Harrison.*) You would not go into matters which you have already dealt with in your previous examination?—Certainly not. I shall avoid as much as possible touching on anything which has been touched upon before.

6919. (*Chairman.*) Are you prepared to offer any observations upon your first point, namely, the ample supply of water to provincial towns?—Yes; with reference especially to towns in Lancashire, for as to the other towns, the Cheshire towns, the Potteries, and all that district, there has been no statement made to the effect that they are supplied properly with water. I have merely to say that all the hill gathering ground that is available in the south of Lancashire, where all the manufacturing districts are situated (they not extending further north than Preston,) is already fully occupied. The whole country is covered over with reservoirs, either for canal purposes, for mill purposes, or for towns supply. I had the honour of submitting to the Commission when I was last examined some maps of that district showing how the whole ground was occupied—more especially in the imme-

R. Hassard, Esq.

19 March 1868.

diate vicinity of Bolton—between Bolton, and Accrington, and Haslingden on the north, the whole country is cultivated, and a working coal-field; to the westward, the hill country is all taken up for the Rivington works, and all draining into the Rivington reservoirs. There is no hill ground except a small portion of Longridge Fell, which is occupied by the town of Preston, and used for the supply of that town, till you get nearly as far north as Lancaster. There is some small portion of gathering ground in the valley of the river Hodder, but that is mountain limestone, and the water is a hard water, which in that country is peculiarly objectionable. That limestone runs across until it joins the Leeds water-shed. The whole of the water in the district of Rochdale is appropriated for that town and for mills and canals. There are several reservoirs in that country at the head of the Rochdale canal. I have further to remark, with regard to this hill gathering ground, that when Mr. Bateman gave his evidence on a former occasion he stated, with regard to a certain area of the country in that district draining into the river Uddlesworth, that it was very improper that Liverpool should have been allowed to absorb it. These were his words, "I think that it was altogether wrong that Liverpool should have been allowed to go to this district, because Darwen, Accrington, Blackburn, Wigan" (which are large towns in that locality) "and many other places are large and flourishing towns closely contiguous to the Liverpool gathering grounds, the whole district having a dense population, where the inhabitants can only look to this little cluster of hills for a supply of water. Liverpool has put its paw upon the supply, and very considerably limited the power of the surrounding districts getting an additional supply of water, and I would venture to suggest, as it is a national question, that if Liverpool should be permitted to go to Bala Lake for water, where it may take water without injury to any manufacturing interest, those hills being as it were the great manufacturers of water, the Rivington district should not be absolutely given up as a supply, but should be held liable to have water abstracted from it for the supply of any neighbouring town which could not otherwise get a supply of water."

6920. Do you concur in that view of Mr. Bateman's?—I do, perfectly. I may state further that there is no gathering ground of sufficient elevation for those towns to be had south of Lancaster, and the difficulty of getting any additional supply of water for the towns in that district is now fully exemplified by the case of Liverpool, where the corporate authorities have been thinking seriously of going to the head waters of the river Lune, to Westmoreland itself, or to the mountainous districts of North Wales, localities distant from Liverpool 110 miles, 90 miles, and 85 miles, respectively.

6921. Following out your view and Mr. Bateman's with regard to the gathering ground appropriated to Liverpool, you are of opinion, are you not, that Liverpool might be supplied or partially supplied out of your general culvert?—Yes, our aqueduct will pass within 200 yards of the Rivington Works. I wish further to state that as regards Manchester itself, which has the reputation of being very largely supplied with water, if the same condition of things existed there which exists in other large towns of similar population, the authorities of Manchester would be now almost at the end of their rope. They would very nearly have exhausted their resources. In Manchester there is a very large quantity of water sold daily for trade purposes, about 7,000,000 gallons a day, I think it is producing a revenue of something like 64,000*l.* a year; and whether it is for the purpose of having more water to sell for trade purposes, or whether it is on account of the difficulty which has as yet been experienced in disposing of town sewage in large quantities, the authorities of Manchester have steadily set their faces against the introduction of waterclosets into the houses of the artizan class forming the bulk of the population of Manchester, and waterclosets there are the exception and not the rule. The privy and ash-pit system is adopted to an enormous extent in Manchester, to such an extent indeed that the corporate authorities actually own rolling stock on several of the railways centreing in Manchester just in the same way that a coalowner owns trucks, and those wagons are used for sending into the country daily the nightsoil cleared away periodically from the ash-pits of the labouring class, and you may see long trains of trucks going every day laden with it into the country.

6922. Is it your opinion that the authorities of Manchester object to a larger supply of water to that town?—No, I do not state that, I say that they have steadily set their face against the introduction of waterclosets.

6923. (*Mr. Harrison.*) Do you know the reason why?—I can only presume that it is either to sell more water for trade purposes, or on account of the difficulty of dealing with the town sewage.

6924. (*Chairman.*) You think that their idea is that by substituting waterclosets for cesspools, the volume of their sewage would be so increased as greatly to increase their difficulty in dealing with it?—That would form one of their reasons, and probably both would operate.

6925. Is that the reason in your judgment why they are not taking an additional quantity of water?—I think it very likely.

6926. The absence of waterclosets does of course diminish the consumption of water?—Yes, very materially. The quantity of water which the Manchester authorities can store on the mean of three dry years would be equivalent to about 33,000,000 gallons per day, and out of that they have to give 14,000,000 gallons for compensation, that would leave them between 19,000,000 and 20,000,000 gallons; probably about 20,000,000 gallons are applicable for trade purposes and for domestic consumption. Out of that they sell about 7,000,000 gallons daily for trade purposes, and that would leave them about from 12,000,000 to 13,000,000 gallons daily for the domestic supply of 600,000 people; and that is the extent of their resources.

6927. That would be how many gallons per head?—About 20 gallons per head, and they cannot get more than that unless they go to some further locality for additional gathering ground.

6928. And by means of your scheme you would give them an auxiliary supply?—Yes. With regard to the towns in the potteries, that large district containing about 200,000 inhabitants, there has been no question raised as to the inefficiency of their supply.

6929. When you gave evidence before, you expressed some doubt, did you not, as to Mr. Bateman's ability to form reservoirs as he suggested in some parts of his district?—Yes, in one particular portion of the district south of Llanidloes, an area of about 15,000 acres which is drained by the river Twylch, I stated that Mr. Bateman could not construct the reservoirs that he contemplated there because the valleys in which he proposed to make them were at that time occupied by a railway, and Mr. Harrison I think it was, said that he thought Mr. Bateman could scarcely have been unaware of the railway being there.

6930. Mr. Bateman has reported that fact to us, that he was not aware of it at the time?—I have no doubt I was perfectly correct in what I stated. Mr. Bateman says that he can construct a reservoir at a place called Babylon in that district which will answer his purpose equally well, but although a site for a reservoir undoubtedly exists there, it happens to be almost at the very head of the drainage area, and it would not command more than about 2400 acres out of the 15,000 acres comprised in the district, and therefore it practically would be of little or no value as regards the storing or the control of the water flowing off it. If you will allow me I wish just to make a statement on the subject of my evidence on a former occasion, as regards another reservoir in that southern branch of Mr. Bateman's scheme, the Trefeglys reservoir. I stated that owing to there being only one reservoir into which all the water both for the towns supply,

and for compensation, whether pure or turbid, must be collected and impounded, in my judgment filtration would at all events for that southern portion of the project be quite indispensable. However, Mr. Bateman thinks otherwise, and he has brought forward Loch Katrine, and adverted to it over and over again as an instance in which water although very highly-coloured I think he stated as brown as coffee, when it entered the loch, yet after exposure there for some time it is drawn off and conveyed for the supply of Glasgow in a state so pure that at a depth of 5 feet some quartz pebbles, perfectly white, appeared only as tinted with a very pale straw colour. But the case of Loch Katrine as compared with his proposed Welsh reservoirs, is totally different; and no comparison by analogy can in any way be drawn between them. Loch Katrine is a reservoir containing an enormous area of exposed water surface as compared with the area of country draining towards it. It also has an immense amount of exposed surface as compared with its storage, as there is only 7 feet difference between the top-water and the level at which the water is drawn off for the supply of Glasgow. I have prepared a table which I will put in shewing the area of Loch Katrine, and the ratio of its exposed surface to its drainage area and storage, as compared with the reservoirs proposed to be constructed for the Welsh scheme:—

The following TABLE shows the AREA of LOCH KATRINE, and the ratio of its Exposed Surface to the DRAINAGE AREA and STORAGE, as compared with the RESERVOIRS proposed to be constructed for the WELSH SCHEME.

Name of Reservoirs.	Drainage Area.	Area of exposed Surface.	Ratio of Exposed Surface to Drainage Area.	Storage in Cubic Feet.	Area of exposed Surface for each Million of Cubic Feet of Storage.
	Acres.	Acres.			
Loch Katrine	22,800	3,000	1/7th to 1/8th	910,000,000	3·3
Llanyddyn, Can Office. Nant-y-Eird and Rhyd-e-gro	66,380	2,645	1/25th	3,493,977,030	·75
Trefeglys and other Reservoirs	64,192	2,200	1/29th	3,215,573,522	·68

It will be seen by this table that Loch Katrine has a drainage area of 22,800 acres, and it has an area of water surface of 3,000 acres. Therefore the proportion of water surface to drainage area is between one-seventh and one-eighth, and as far as regards the towns supply, there is a difference between the top-water and the level at which it is drawn off of 910,000,000 cubic feet, and that gives an area of $3\frac{1}{3}$rd acres for each 1,000,000 cubic feet which is impounded in the loch. The northern branch of the Welsh scheme has a drainage area of 66,380 acres, and a reservoir surface of 2,645 acres. Therefore in this case the ratio of the surface of the reservoirs to the drainage area is only $\frac{1}{25}$th, that is to say they have only one acre of exposed surface for every 25 acres of drainage; and they have only three-quarters of an acre of exposed surface for every 1,000,000 cubic feet impounded in the reservoirs. And in the Trefeglwys reservoir which is the one I am particularly alluding to, they have less again. In the Trefeglwys and two smaller adjacent reservoirs, the drainage area is 64,192 acres, whilst the area of exposed surface is only 2,200 acres, being $\frac{1}{29}$th of the drainage area: that is to say one acre of exposed surface for every 29 acres of drainage, and they have only two-thirds of an acre exposed surface for every million cubic feet impounded, instead of $3\frac{1}{3}$ acres as you have in Loch Katrine, so that there is no analogy whatever between the two cases.

6931. Taking what we may call the bleaching area of Wales, is it your opinion that it would be insufficient to remove that colouring matter from the water? It would have some effect upon it, no doubt; but nothing like the effect that is produced in Loch Katrine. The area of Loch Katrine as compared with the drainage area is between four and five times as great as it is in those Welsh reservoirs. In Liverpool, where the water both for supply and compensation is impounded in the same reservoirs, filtration is found to be indispensable; and even then the objections raised against it on the scale of colour are so great that they have to mix it with water pumped from the new red sandstone.

6932. Mr. Bateman drew a contrast between the cost of forming reservoirs in the Welsh district, and the cost of deepening the natural reservoirs in the lake district, and of the several communications necessary to work your system. Have you anything to state upon that subject?—Yes. Mr. Bateman has given the cost of collecting the water and of constructing reservoirs in the Welch district at 1,060,000*l.* as against our estimate of 1,013,000*l.* for the same description of work in the lake district, which estimate Mr. Bateman does not dispute. But then in making that comparison Mr. Bateman has taken the cost of only one branch of his scheme, that is the northern branch, for supplying 130,000,000 gallons, and he has compared that with the whole expenditure which is to be incurred in impounding water in our scheme for the supply of 250,000,000 gallons daily. If we add to that the cost of collecting and impounding the water in the southern branch of Mr. Bateman's scheme, it makes a total amount of 2,200,000*l.* as against our 1,013,000*l.*, being a balance of 1,187,000*l.* in our favour.*

6933. (*Mr. Harrison.*) Are those Mr. Bateman's figures?—Yes, copied from his evidence. To institute a comparison between the two projects, of course, the cost of impounding in both branches of Mr. Bateman's scheme ought to be added to it so as to compare it with the total cost of ours.*

6934. (*Chairman.*) I suppose that nothing you can say will shorten the distance between the lakes and the metropolis?—I have something to say upon that. Mr. Bateman states that the district from which he proposes to take water is distant only 170 miles from London, whilst he states that ours is 270 miles, being a balance apparently of 100 miles in Mr. Bateman's favour. But in order to institute a fair comparison between the two, Mr. Bateman should have added the 23 miles of additional aqueduct which he is obliged to construct in order to bring in the water from his southern branch, which would make it 193 miles of aqueduct to bring the water from Wales, as compared with 270 miles to bring it from the lake district. So that although our locality is more distant than Mr. Bateman's, still the difference is not to the same extent as he has stated.

6935. What is the size of the tunnel in that 23 miles as compared with the main culvert?—Mr. Bateman's open aqueduct in the southern branch is 22 feet wide as compared with a width of 26 feet $4\frac{1}{2}$ inches in the main aqueduct, and the covered aqueduct has a width of 12 feet 6 inches as against 16 feet 6 inches in the covered conduit for the main project.

6936. Taking that view of the case you have 77 miles against you instead of 100?—Yes.

6937. Mr. Bateman estimates the cost of his works as against yours and charges you with the cost of 100 miles, but you reduce that by the explanation which you have given by 23 miles?—Yes.

6938. Namely, by reducing the estimate of distance as between you and Mr. Bateman to 77 miles?—Yes.

6939. Which will proportionately reduce the contrast which Mr. Bateman institutes between his scheme and your scheme?—Yes.

6940. (*Mr. Prestwich.*) That would apply, would it not, only to a part of Mr. Bateman's scheme?—The distance that a locality is away from a town virtually

* See explanations in questions 7159 and following.

R. Hassard, Esq.

19 March 1868.

depends upon the length of aqueduct that you have to construct in order to bring the water from that locality and therefore to make a fair comparison between the two projects you must add the length of that branch which is 23 miles to his main aqueduct and his other branch aqueduct.

6941. But that would only apply to one branch of his scheme ?—That is so.

6942. (*Mr. Harrison.*) It would be the difference between 23 miles of a full-sized culvert and 46 miles of a smaller culvert ?—That would be it.

6943. You branch off into two, and they are two of a very much smaller size ?—Not quite so much as you have stated, because the larger branch is not quite so long, but about 44 miles as against 23 miles.

6944. Then there is the difference between 44 miles of the small culvert and 23 miles of the larger culvert ?—Yes.

6945. (*Chairman.*) Have you anything further to add upon that point ?—Nothing.

6946. Then there was some question, was there not, as to the difference of fall between your scheme and Mr. Bateman's ?—Yes. There is no doubt that Mr. Bateman can give a greater fall to his aqueduct than we can. I do not dispute that for a moment, but I maintain that no great advantage of economy arises in consequence of that, because the fall which we have selected is that at which it is most economical to construct and to work works of that nature, and I shall show shortly that the fall which we have given to our aqueduct is such as to cause that velocity considered most advantageous in great works of this nature by all engineers who have had experience in the matter. It has been very largely adopted by Mr. Bateman himself amongst others. On the subject of fall I would wish to mention that there is an error of about 20 feet in some way connected with the difference of level at which Mr. Bateman stated that he could deliver the water in London. He has given the falls of his conduits in his evidence, and he has stated that he could deliver in his reservoir in London at an altitude of 270 feet above Ordnance datum. There has been some error which will not materially affect the question, but there has been an error of about 20 feet in that. He draws off from the reservoir at Rhyd-e-gro, which is the lowest reservoir on the northern portion of his project at a height of 450 feet. From that to the junction of the two branches at Marten Mere there is 5 miles open conduit with a fall of 6 inches per mile—that is 2 feet 6 inches; he has 12 miles of covered aqueduct, with a fall of 14 inches per mile—that is 14 feet; and he has 2 miles of syphons crossing the Severn, with a fall of 5 feet per mile, which gives 10 feet, being a total fall on the northern branch of 26 feet 6 inches, and that deducted from the height at Rhyd-e-gro of 450 feet leaves a height at the junction of the two branches of 423 feet 6 inches. Then from Marten Mere to London for the main aqueduct he states that he has 75½ miles of open conduit at a fall of 6 inches per mile, being 37 feet 9 inches. Then he has 65 miles of covered conduit, with a fall of 14 inches per mile, giving 75 feet 10 inches, and he has 11½ miles of syphons, with 5 feet fall per mile, giving 57 feet 6 inches, making a total of 171 feet 1 inch, and that deducted from the 423 feet 6 inches, which is the height of the commencement of the main aqueduct, leaves 252 feet 5 inches as the height at which the water could be delivered at Stanmore, and not 270 feet, as he has stated. That error does not affect the question very materially, but Mr. Bateman took some credit for the particular height, and he stated that he could deliver water more conveniently from it to the existing reservoirs.

6947. Mr. Bateman stated that at your height you would be unable to deliver your water into the mains of all the companies; do you agree with him in that ?—That I shall come to presently, but he took particular credit for that height of 270 feet, as it enabled him to distribute very conveniently to all the service reservoirs of the existing companies.

6948. (*Mr. Harrison.*) There would be no difficulty, would there, in his so arranging his fall as to deliver it at that height ?—No, but it would be coming to something like our dimensions and our fall.

6949. What is your height ?—We deliver at a height of 232 feet 6 inches, and he says that he will deliver at 270 feet.

6950. (*Chairman.*) The next point raised by Mr. Bateman is a very important one, namely, that your wrought-iron tubes for syphons with a fall of 1 foot 8 inches per mile would be insufficient—have you any explanation to give of that ?—Yes, I have. In the construction of syphons the question to be considered is, not altogether the fall that you give them, but it is the velocity with which the water will pass through them, the fall being one ingredient only which causes the velocity. In a 4-feet pipe, with a fall of 5 feet per mile, such as Mr. Bateman contemplates for his works, each pipe would deliver about 2,320 cubic feet per minute, or about 20,880,000 gallons per 24 hours, and the water would pass through it with a theoretical velocity of about 185 feet per minute; and if we add 25 per cent. to each of those figures, as Mr. Bateman has done, owing to the excess which the Glasgow pipes were found to deliver over their theoretical quantity, it will give the water passing through a velocity of 220 feet per minute, and a discharge of 26,100,000 gallons per 24 hours. But an 8-feet pipe, with a fall of 1 foot 8 inches per mile, will deliver theoretically 7,560 cubic feet per minute, equal to 68,100,000 gallons per 24 hours, and the water will pass through it with a velocity of about 150 feet per minute; and if we add 25 per cent., as in the other case, we shall have a velocity of 187 feet 6 inches per minute, with a discharge of 85,125,000 gallons per 24 hours. Therefore, although the larger pipe has only one-third of the fall, still the water will pass through it with a velocity equal to about 6-7ths of what it attains in a smaller pipe with a greater fall.

6951. (*Mr. Harrison.*) That is a point which merely affects the question of estimate, because if you require to have two pipes there is no difficulty in getting the quantity of water through; it would be only a question of estimate arising upon it ?—Economy was one of the reasons why we contemplated the use of those large pipes. A cast-iron pipe, 4 feet in diameter and 1½ inches thick, which it would be required to be on the average for standing this pressure, will weigh per mile 1,888 tons.

6952. Did you not, in your former evidence, give your reasons for adopting wrought-iron in preference to cast iron ?—I think I only gave the discharge. I do not think I gave the cost, or that I gave the reasons for adopting the larger pipes. I do not think I stated anything about the comparative cost of the two, but if I did I will not go further into that point. I wish to say just one or two words upon the subject of coating the pipes with Portland cement. These were the reasons which Mr. Bateman gave why in his judgment it would not be successful. He stated that it would be necessary to wet the iron in the first instance, which would cause it to rust, and that the cement would then scale off and afford no protection to the pipes, and he brought forward a variety of reasons why in his opinion that must certainly occur; but as regards that I have only to say that it is one of those instances in which a little practice is worth a great deal of theory. We produced a pipe before the Commission which was coated in that way with a lining of cement 5-8ths of an inch in thickness. That pipe was made at Middlesborough-on-Tees, and was made for the purpose of this experiment. It was brought up to London and was lying about in one place or another exposed for a fortnight before the coating was put upon it. Since the time I had the honour of submitting it to the Commission, which is rather more than 12 months ago, it has been lying in London on an open wharf. It has been exposed to all the differences of temperature between great solar heat and extreme frost; it has been rolled off a cart; it has been kicked about in every way; and yet the

cement adheres now so closely that it is perfectly intact, so much so that you cannot detach it from the metal except by a hammer and chisel.

6953. Do you consider that the introduction of those wrought-iron pipes and this cement is an essential feature of your plan?—No, I do not, but I say that it would be a very great protection to the pipes. As regards the use of cement for protecting the iron, at a discussion which was held at the Institution of Civil Engineers on the strength of cements, the matter was fully gone into, and Mr. Rawlinson instanced a case in which he had used Portland cement for making a water-tight joint between two cylinders, used in sinking a well, one being sunk inside the other and that he used it successfully for making a joint under a 90 feet head of water. At that time it had been in operation about three or four years, and had been subjected to all the shocks consequent upon heavy pumping, and yet it had remained perfectly intact. And on the same evening Mr. Scott Russell stated that Portland cement was extensively used for lining the insides of iron ships to protect them from the effect of bilge water. He instanced a case where he himself had seen cement dug out of the side of an iron ship which had been put there 18 years before, and that the paint and the skin of the iron were as sound as when the cement was first placed there. I submit that that is a pretty strong proof of the applicability of the material for the purpose.

6954. It never has been practically applied has it to water pipes for any period of time?—Not that I am aware of. I may mention that it was the tenacity with which I had remarked that Portland cement adhered to the polished surface of a trowel if a bricklayer left it for two or three days without cleaning it, and the difficulty of detaching the cement from the polished surface of the iron, which induces me to think of it for this purpose.

6955. (*Chairman.*) Would the application of Portland cement as a lining to these pipes add much to the friction?—It would reduce the friction very materially, because the cement is as smooth as marble; it is as smooth as plasterers work, much smoother than the iron itself.

6956. How do you form the joint, do you grout it in?—The way that we propose to apply it is by rendering it inside after the pipes are in place. That was the way that that piece I mentioned was done. It was not done at the bottom first and then turned over, but it was done *in situ*. The inside was rough cast in the first instance, just as a plasterer does a wall with cement, and it adhered at once to the iron, and in the course of a few hours after that there was a coat of cement put on about $\frac{3}{8}$ths or half an inch thick, and then there was a fine finishing coat about $\frac{1}{8}$th of an inch thick put on after that, altogether a thickness of about $\frac{5}{8}$ths of an inch. As regards the applicability of wrought-iron for these purposes, all that I have to say is that it is used for works of the same nature. Mr. Bateman has used it in his aqueducts for carrying the water into Glasgow and Mr. Bazalgette has used it extensively in the aqueducts of the metropolitan main drainage. Some years since, I forget how many, but I think it was seven or eight years since, there was a wrought-iron pipe of 7 feet 6 inches in diameter and 1,300 feet in length laid down in connexion with the Croton works supplying New York with water. That has been in operation seven or eight years certainly. And two large wrought-iron pipes, each I believe 6 feet in diameter, (and technically called by the Americans flumes) for conducting water to two large turbines at Lowell in the United States, working under a head of 30 or 40 feet of water, and driving the machinery of a very large mill, were constructed either 29 or 30 years ago. I read a description of them some time ago, in one of the engineering journals, and made a note of it at the time. The water was conducted by two 6-feet wrought-iron pipes to those turbines, and the metal was quite unprotected. They had been recently examined at that time, and the wrought iron was found in very good condition, whereas the cast iron which formed the junction chambers of the wrought-iron pipes with the turbine case was completely eaten into holes.

6957. (*Mr. Harrison.*) Were they buried in the earth?—Yes, they were buried in the earth and subjected to the pressure of water internally, so that as far as regards wrought and cast iron in that particular case the wrought iron was much more durable than the cast iron. The Loch Katrine aqueduct into Glasgow has several wrought-iron tubes.

6958. In that case it is exposed and painted, is it not?—Yes; they are suspended. I do not know whether they are painted internally or not, but they are ordinary troughs for the conveyance of water. The pipes might be protected both internally and externally with cement.

6959. (*Chairman.*) Some question was raised as to the difficulty of forming your tunnel under Kirkstone pass; have you anything to remark upon that?—Mr. Bateman did not say that the thing could not be done, but he seemed to consider that the central length of $1\frac{3}{4}$ miles between the shafts was a most serious objection, that it would very greatly delay the completion of the scheme, and he instanced the length of time which was occupied in driving the tunnel leading out of Loch Katrine, although they had a number of shafts in it, and he seemed to infer that according to the rate of progress there, our tunnel would occupy such a length of time that it would be almost prohibitory. When I gave my evidence before, I referred to the Mont Cenis tunnel and gave evidence of the rate of progress during the years 1863, 1864, and 1865, and the rate of progress effected during the last two years. In 1865 it had attained an average of 5 feet 6 inches per day, at each of the two working faces, and since that time I have seen and examined the two published returns for the years 1866 and 1867, and the rate of progress effected during those two years has averaged as nearly as possible six feet per day at each of the two faces. At that rate of working, the Kirkstone tunnel would be pierced through in two years and five months after the shafts were sunk, taking 313 days as the working year. In that particular case, owing to the height of the mountain, you could not sink shafts; the summit is about 1,100 feet.

6960. Have you anything further to add upon that point?—Not on that subject.

6961. What observations have you to make upon the comparison between the cost of Mr. Bateman's scheme and yours involved in the mode of construction?—The same circumstances do not apply to both cases. For the first 120 miles of our aqueduct, from Ullswater southwards, it passes through a country abounding in building material of the very finest quality and in every way suitable for the purposes of the works; in fact, much of the aqueduct is excavated in the stone itself, and I maintain that no prudent engineer would discard that admirable material which is to be had upon the spot and at a very small cost, in favor of brickwork to be brought from some distant locality at considerable expense. That was not the mode of construction which Mr. Bateman adopted himself in the Loch Katrine works, or in his Halifax works; he there used as much as possible the material that he found upon the spot, and he takes credit to himself for having done so. Here are drawings of the Loch Katrine aqueduct (*producing the same*) and you will see that the works are almost entirely constructed with the rubble of the country itself. At Halifax where there is building material, all the conduits between the impounding and the service reservoirs are constructed of stone.

6962. (*Mr. Harrison.*) Do not you assume that he would avail himself of the material of the country, as every engineer must do?—Yes. But I was about to state further that from the Potteries to London we are pretty nearly similarly circumstanced with Mr. Bateman, and we there propose to use concrete and brick as he proposes to use concrete and brick for his aqueduct, and there is really no material difference between us. We use more concrete and rather

R. Hassard, Esq.

19 March 1868.

less brick, he prefers to use more brick and less concrete, but there is really no very great difference between us. It is only in the northern portion of the project that we propose to use the material that we find upon the spot. From the Potteries to London we pass through a clay country, and from the River Severn to London Mr. Bateman also passes through a clay country, and he cannot avail himself of stone.

6963. In the other portion of it he goes through a great deal of country where for some distance he has stone?—Yes; west of the severn he would have stone certainly, but that is but a comparatively small portion as compared with the whole.

6964. (*Chairman.*) Will you have the goodness to state your views with respect to the Edgware reservoir?—Mr. Bateman stated that at the elevation at which we propose to construct our reservoirs no sites for them could be found. Those two reservoirs of ours will contain together 500 acres.

6965. (*Mr. Harrison.*) Did you in your original scheme go to the same place?—Mr. Bateman proposed Stanmore; we proposed Edgware all along, and latterly Mr. Bateman has proposed Stanmore and Edgware, we neither take a house or a road, and we have every advantage that Mr. Bateman claims. Although Mr. Bateman stated that at the elevation at which we proposed to construct our reservoirs no sites could be found, I am satisfied that we should have no difficulty whatever in constructing our reservoirs.

6966. Have you taken the levels of those proposed reservoirs at Edgware?—I have not, but I am satisfied about it, and I see no difficulty in forming an estimate of the cost. There are a great many levels on the map by which I was guided.

6967. (*Chairman.*) Having regard to the site which you have selected for your reservoirs, should you be able to deliver water to the Maiden Lane reservoir of the New River Company?—I have got the height of their reservoirs from a map published by Mr. Milne showing the works belonging to all the water companies in London, and that reservoir was there given as at a height of 219 feet, and it was in order to be able to deliver into it that I was guided in determining the height at which we proposed to deliver at Edgware, so that either Mr. Bateman has made some mistake or Mr. Milne has made some mistake as regards the height of that reservoir. But even if it is as Mr. Bateman states, there would be no great difficulty in slightly altering the level of that reservoir and putting the houses on the highest service immediately in connexion with it in connexion with a reservoir just above on the same system. It might be a matter of some expense altering it, but that is a case which would not be sufficient to weigh in a scheme of this nature. Mr. Milne's height is 219 feet above ordnance, and Mr. Bateman's is 231 feet.

6968. (*Col. Harness.*) Have you both assumed the same datum level?—Yes, both the ordnance datum.

6969. (*Chairman.*) Is there any question as to the capacity of the reservoirs?—Mr. Bateman stated that the contents of our reservoirs are not sufficient, but we have taken just the same sum for their construction as he has, and we can consequently make them of the same capacity; they are on the same spot.

6970. (*Mr. Harrison.*) It does not follow that you can do it without having taken sections; it is quite possible that you might not be able to do it?—The hill is on the same slope all through, and there can be no difficulty whatever about it; there can be no material difference in the ground in both cases.

6971. (*Chairman.*) Are we to understand that the calculations to which you have referred will be ready by this day week?—Yes.

6972. (*Mr. Harrison.*) In the estimate which you gave originally to the Commission, after reaching the Edgware reservoir, what was the additional estimate for distribution as far as you could give it?—As regards the position of the reservoir I stated "About "a mile north of Edgware is the place where we "propose to construct the service reservoirs; we "should have them in duplicate, so that one might be "cleansed while the other was in use."

6973. What did you estimate from those reservoirs to the point of delivery to the different companies?—I do not think that that question was gone into at the time either by Mr. Bateman or by us, and the estimates that Mr. Bateman has given in have it as a subsequent calculation altogether. I do not think that either Mr. Bateman or ourselves contemplated anything further at that time than the reservoirs at that place. We have 500,000*l.* down for them, and Mr. Bateman had the same figure in his pamphlet. I do not think he gave it in his direct evidence. In ours we did not go beyond the construction of service reservoirs at Edgware. We considered that 250,000*l.* would be sufficient to construct the reservoirs, and that we should have 250,000*l.* for connexion with the existing works.

6974. Do you propose to adopt the same plan of connecting your reservoirs with the existing service reservoir as Mr. Bateman has described?—I have seen his statement so lately, only within the last two or three days, that I have not had time to think of it; but when I am giving evidence as to the estimates I will give some evidence upon that subject.

6975. In the Lancashire district you say, do you not, that many of the millowners have got their own reservoirs for supply?—A great many of them.

6976. But none of those reservoirs are of sufficient capacity to hold all the flood water?—Generally not.

6977. In fact the district there is similar to what most districts are when you come to make waterworks. You have to make provision for supplying them in some way; they do not absorb the whole quantity from the water shed?—They do not absorb all the water to be got off the district.

6978. Then the evidence this morning would go rather to express an opinion that the whole of the water of that Lancashire district is already used and could not be applied further?—The millowners' reservoirs are not sufficient to control the whole of the flood water, there is no doubt of that.

The witness withdrew.

Adjourned to Wednesday next at 12 o'clock.

Wednesday, 25th March 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS, C.B.	JOSEPH PRESTWICH, Esq.

Sir BENJAMIN BRODIE, Bart., examined.

Sir B. Brodie, Bart.

25 March 1868.

6979. (*Chairman.*) You are, as we all know, professor of chemistry at Oxford?—Yes.

6980. Has your attention been directed to the quality of water used for domestic purposes?—I have been much interested in the question of the drainage of Oxford, and it is through my connexion with the drainage question at Oxford that I have been indirectly connected with the water question, but I should say that otherwise I really have not paid any considerable attention to the subject.

6981. Have you considered the effect on the human system of hard and soft water?—No, not as hard and soft water.

6982. You state that your attention has been drawn to this subject mainly in connexion with the drainage of the town of Oxford, have you made any experiments as to the condition of the water where a discharge of sewage has taken place?—I have not made any direct experiments upon that subject; but I live on the river at Oxford, just by a place where, unfortunately, a great drain falls into the river, so that I have a daily opportunity of witnessing its effects.

6983. Where the sewage has been discharged into the river and carried down by the current for a few miles, have you observed a difference between the condition of the water at that point and the condition at the point of discharge?—There certainly is very soon a difference in the condition of the water. My house is only one or two hundred yards below the point where a large sewer is discharged into the river, and yet at my house the weeds freely grow in it, and I do not think that, except for the turbidity of the water, you would say that the river was impure.

6984. Do you know at all the relative proportion of sewage as compared with the quantity of water flowing down the river at that point?—No, I do not; but occasionally you can see the sewage in the river.

6985. I presume it is a large volume of water as compared with the quantity of sewage?—There is occasionally a very large volume of water, but not always.

6986. It has been stated in evidence before this Commission that in the case of sewage discharged at Windsor into the river, and flowing down the stream six or seven miles, or rather more, at that point they have failed to detect the presence of the sewage, that from oxidization or the breaking up of the elements it is in such a condition that they have found nothing which in the judgment of the witness would be prejudicial to human health. Have you made any observation bearing upon that point?—I have not myself made any observations on that point, and, indeed, I do not know how such an examination could be satisfactorily conducted.

6987. A sample of water was taken out of the river immediately below the point where the sewage was discharged into it, and a sample was taken out seven miles below that point, and by instituting a comparison between the two waters, in the one case of course they could detect the presence of sewage, and in the other they failed to detect it?—The judgment of the witness on such a point could be of literally no value whatever, unless the method employed by him for the detection of the prejudicial matter of the sewage were really of such a nature as to justify him in pronouncing an opinion upon the subject. I do not know what the method employed for the detection of the sewage was and whether that method was adequate for its detection or not, but I may say with confidence that chemical methods for the detection of the sewage are extremely imperfect. Indeed I do not know of any adequate method for the examination of water for sewage.

6988. Have you formed any opinion as to the probable effect of the flow of seven miles upon water contaminated with sewage, whether at the end of that distance or any other distance it would be fit for human use, or could be considered to be a safe water?—The sewage would be during its course to a certain extent oxidized and destroyed, and resolved into other compounds, but how should we say that all the sewage is resolved and destroyed so that the water should be safe. To do that we must be able to apply some extremely sensitive test to the water which would enable us to ascertain the presence or the absence of sewage in it, and I want to know what the test is which we are so to apply. There are causes operating, as we all know, to destroy the sewage which, to a certain extent, will effect that end, but the question, as I understand it, is whether those causes are really adequate to destroy the sewage not partially, but absolutely and entirely, during a given course of the river.

6989. The question is, whether by the operation of Nature's own course, by the water flowing exposed to the air and becoming oxidised, the effect would be to free it from injurious elements thrown in in the shape of sewage, to such an extent as to render it fit for a supply of water for domestic purposes, and free from objections with regard to the health of the inhabitants?—I should certainly be sorry to pronounce a positive opinion either that the water was fit or was absolutely unfit for such purposes. Let us take an analogous case. Suppose that I were to take a glass of water and placing it before me on the table here, and I were to put into that tumbler of water a teaspoonful of sewage, perhaps one per cent. of sewage, and then I were to take, which I could easily do, an apparatus by which I should blow air through the tumbler of water, so as to effect its constant aeration, restoring to it the water evaporated, the question is at what time would that tumbler of water become in such a state that any one of us would be willing to drink it off, how many days, weeks, months, or years would elapse? That I understand to be the problem, and I am sure I cannot solve it; but I can only say that when you have once put sewage into the water I should be rather reluctant to drink it.

6990. You have made no experiments, have you, with a view to ascertain that poin t?—I have made no experiments to ascertain that point. I have seen accounts of experiments by others. I do not know what the experiment would be worth if it were made.

6991. You have been supplied with a copy of the medical evidence which has been laid before the Commission, and no doubt you have observed that we have had evidence on both sides, one party alleging that water impregnated with sewage will be purified by the action of the air and oxidisation in its course a few miles down the river, but on the contrary, Dr. Frankland states very distinctly, that water once contaminated with sewage is unfit for human use, and that you will still find what he calls the skeleton of sewage present, although it may have travelled 100 miles and been exposed to filtration?—I think what is asserted by Dr. Frankland is true, that there are no known causes in operation on which we can adequately rely to remove the sewage from the water. That causes are in operation which partially remove that sewage and diminish its injurious effects is true, but the question is whether those causes, as I said before, are adequate to produce a complete result; that is to say, whether they will take out of the water all the injurious matter which is contained in it, so as to render it fit for drinking. I do not think it possible, in the present state of our knowledge, to pronounce an absolute opinion upon that point. But if you ask whether it is wise to drink water into which you have put sewage, knowing that you have no positive means of getting that sewage out of it, that is a question which anyone can answer for himself, assuming always the injurious character of sewage. I am not now pronouncing any opinion upon that point, or saying in what degree sewage is injurious; that does not appear to me to be a chemical question. I think that is a question of very great importance, but which is much more likely to be solved by other agencies than by chemical experiments. Medical statistics will tell you more about the injurious or non-injurious character of sewage water than any analysis would do. It does not seem to me that we have, as I before said, any accurate chemical measure of the sewage in the water at all events, I do not know what that measure is. I have read the evidence which has been given by Dr. Frankland and one or two other witnesses also before this Commission, but I still hold to my opinion that we have no accurate measure of the sewage matter in the water, or even of the previous sewage in the water.

6992. Are you prepared to express an opinion on the result of the application of sewage to the land, the water being afterwards discharged into a river,

Sir B. Brodie, Bart.

25 March 1868.

whether it would or would not be injurious to health after its filtration through the soil?—No; I think here again the same obscurity prevails, only to a less extent. I think it is certain that the sewage-water must be benefited very materially indeed by being filtered through the land, and I have that opinion because I know that in the porous material of the land the processes of oxidisation which destroy the injurious sewage matter go on much more rapidly and efficiently than they do otherwise, and not only that, but that the land operates as a filter and stops, mechanically, a large portion of the solid injurious matter of the sewage; but if you ask me whether the water that runs out from the land, although it may be bright and clear, is a good beverage, I do not know how we are to answer that question except by giving the water to human beings to drink, and by long observation of its effects.

6993. Then, although the process of filtration may catch and retain all that is held in mechanical suspension, still in your judgment there may be elements passing off in solution that might be injurious to health?—I think there may be, certainly, and not only in solution, but even not in solution; I mean by that that there may be even solid matters, organic germs, which would be so small that they would pass through the filtering material employed.

6994. And which might be unobservable to the the eye?—Unobservable altogether to the senses, and yet which might be extremely detrimental to the health; but here again you cannot say that they are detrimental to the health, you can only say that they may be so.

6995. Has your attention been directed to the effect upon the water of coloring matter from the peat, or whether it is possible to get rid of it by exposure to the atmosphere, or any other mode of precipitating it?—I have not turned my attention to that subject.

6996. (*Mr. Prestwich.*) You have read the evidence of Dr. Frankland, and I presume of Mr. Wanklyn, with regard to the methods adopted for the determination of organic matter in water?—Yes.

6997. Those methods, no doubt, show the great improvements which have taken place during the last few years in the chemical analysis of water, but you think them still imperfect, with regard to the determination of the organic matters connected with the question of previous sewage contamination?—I think that they are imperfect both as regards previous sewage contamination and as regards actual sewage contamination. I ought to explain myself; Dr. Frankland's method really seems to do pretty well what is possible without inventing decidedly new processes. But one reason why I think that Dr. Frankland's method is to a certain extent imperfect is this, that the amount of nitrogen and of carbonate to be determined is altogether very small, and no adequate account is given of the errors of the method, so that I am not able to say from simply looking at the documents that I have had before me what the value of those analyses or those determinations is. To know what the value of an analysis is, we must know to what errors that analysis or method is subject; and I have not had put before me in this evidence, or I must have passed it if there, any statement of investigations of a sufficiently exact character as to the error of the method, which in this case is a point of fundamental importance. Now, this is not a matter which need be left in the dark, for I think it would be really possible to get at those errors. One very simple course would be to make not one or two analyses, but a large number of analyses of the same water, for it would be quite possible from a large number of analyses to infer what the error was to which the method was subject. And I think it would be a very good thing for the Commission to have placed before them some table of that kind indicating the probable error of the method.

6998. (*Colonel Harness.*) You mean in order to get at the probable error of a single observation?—Yes; a single observation tells me nothing at all. If a person tells me that he has found by analysis so much nitrogen as nitrates, and so much as organic nitrogen, I cannot tell simply from such a statement anything about it. I must know to what error that analysis is subject, that is, to what extent his statement is trustworthy, because it is possible, I am not saying that this is the case here, but it is possible, that the error may be even greater than the quantity of nitrogen to be determined, and I think it would be quite possible, as I say, for the Commission to get evidence upon that point.

6999. (*Mr. Prestwich.*) You mean by a given number of analyses being made of each sample?—I do not say that that should be done in every case, it would be very laborious to do it; but if you were to take one or two selected samples and have a great many determinations made of them, the more the better, you would then see, or at least you would have more chance of seeing than now, what conclusions you were really to draw from the analysis.

7000. (*Chairman.*) Are we to understand that the several analyses which you suggest to be made should all be made from the same water taken at the same time, or do you mean water taken at different periods?—I mean analyses of one and the same thing. Dr. Frankland, I believe, has to a certain extent investigated this error, as was pointed out to me just now, in a paper of his which was read before the Chemical Society, but as far as I understand his method it is not that which I suggest.*

7001. (*Mr. Prestwich.*) Would the analyses of the London waters which give the mean of a number of analyses made every month in the year be what you want?—No, that tells me nothing at all as to the point in question. If you tell me that water contains such and such a decimal per-centage of organic matter, that tells me nothing unless I know what value is to be attached to the observation, and one way of getting information on this point, which should not be neglected, would be to make a great number of analyses of one and the same water for the sake of trial by the same method and the same observer if you can.

7002. With regard to the method employed by Dr. Frankland, I presume it is most complete, and that he brings to bear upon it all the most recent and improved processes?—I imagine that to be the case. Certainly there is no more admirable analyst than Dr. Frankland.

7003. The way in which Dr. Frankland, in the tables which he has handed into the Committee, ascribes so much nitrogen to organic nitrogen and so much to other causes may, however, probably be open to a difference of opinion?—There are, un-

---

* The witness subsequently added the following remarks:—

The first series of experiments instituted by Dr. Frankland in elucidation of this point [Chemical Society, Quarterly Journal, vol. vii. p. 94] do not throw much light upon the question, for we can hardly argue from the determinations there given in the case of urea and of hippuric acid as to the probable error in the case of so different a material as sewage. The experiments, however, which are subsequently given [xii. p. 95] meet the case, and if sufficiently numerous and varied would give an answer to the proposed question.

The three series of experiments there detailed may be regarded as analyses of one and the same water, it being assumed (which is implied, although not stated,) that the same sewage matter was employed in the three series of experiments.

Thus regarded, experiment I. (100 Cl sewage, 900 Cl water) being taken as the starting point, the relative proportions of carbon and nitrogen in 100,000 parts of the water evaporated appear as follows:

Experiment.	Carbon.	Nitrogen.
I.	1·00	1·00
II.	1·09	1·00
III.	1·65	1·21

Dr. Frankland cites these experiments as tending to inspire confidence in the method employed. The divergence, however, between experiment I. and III. of 65·5 per cent. in the carbon and 21 per cent. in the nitrogen, is so large a proportion of the whole amount to be estimated, that, *from these data alone*, no reliable opinion could be formed as to the amount of sewage matter present. Experiment III. hardly justifies the assertion that by this method one part of sewage matter in 100,000 of water can be detected, since if experiment I. is to be assumed as the true result, in experiment III. the error is equal in amount to 0·65 parts of the whole carbon present.

doubtedly, several questions which give ample room for difference of opinion, there is the observation and the value that we are to attach to the observation, and even then it is a farther question how you are to interpret the analysis, supposing it to be correct.

7004. In all those analyses a certain value is ascribed to previous contamination, as determined by the presence of nitrates and nitrites in the water; will you give your opinion whether the presence of nitrates and nitrites is to be ascribed to that one source alone, or may it be ascribed to several sources?—I think the probability would be that the presence of a large quantity of nitrates and nitrites would indicate the previous presence of organic matter in the water; but I do not know that you could take that nitrogen, in the shape of nitrates, as an absolute measure of that organic matter, which is a different thing.

7005. I presume that when those salts are in large excess, there is little doubt that they may be ascribed to sewage?—It is, I should say, the most ordinary source of nitrates and nitrites.

7006. But is it not possible that in many cases such salts may be derived from other sources than that of previous sewage contamination, using that term in its common acceptation; may they not arise from other matters in the soil, and therefore is their presence a fair indication of previous sewage contamination?—I believe that nitrates may occur from other causes, but I cannot speak from positive experience.

7007. The main object to be sought for in water used for drinking purposes is not the presence of a small quantity of nitrates or nitrites, which would not be very important, but the presence of organic matter undecomposed; is not that so?—That would be, no doubt, the most important as well as the most difficult point to be determined.

7008. If you will turn to the table of Dr. Frankland you will see, in the column of the mean of organic nitrogen, that the quantities in the London waters vary from ·001 to ·011, and those in the waters from Lake Katrine, Manchester, and Lancaster, from ·001 to ·026; showing, therefore, little or no difference in the quantity of organic nitrogen. Have you paid attention to the conclusion drawn by Dr. Frankland that it is possible to determine the origin of this organic nitrogen by the proportion of organic carbon that may be in the waters?—No, I have not until now seen the tables referred to.

7009. Dr. Frankland considers that this organic nitrogen in the London water is of a different value from that in the lake waters, because the proportion of organic carbon to the nitrogen in the waters is different?—Yes. This appears to me a very important fact, and may really indicate that the organic matter in the water had, in the two cases, a different origin.

7010. Supposing that a certain quantity of organic matter were introduced into the water, it would only be a question of the length of flow of the river as to whether or not the sewage would be perfectly oxidised?—We know that the process of oxidisation does go on with very considerable rapidity under certain conditions of temperature, or in a porous soil; but, as I said before, how are we to say when that oxidisation is absolutely complete?—I do not know what crucial test you could apply to bring out that point, whether it is complete or not. The putting sewage into a river is a plain fact, as to which there can be no doubt; but what we do not know is, when you bring the sewage out of the river, and I do not see that any test has been given which is of a sufficiently accurate and delicate character to bring out that point.

7011. You think that the tests of the greatest delicacy are yet insufficient to determine the point at which sewage ceases to be present?—I may take a case which really is an absolutely analogous case to the case of water, namely, the case of the atmosphere. You may look at the atmosphere as really a great ocean. Gases from drains are being discharged into this gaseous ocean just as the water from the drains is going into the river. Those gases are so diluted when they get into the atmosphere that chemical analysis is absolutely impotent to reveal their presence in any given portion of the atmosphere. But nobody can doubt the injurious effect, under certain conditions, of the gases and other organic matters present in the atmosphere. Take the case of the Westminster drain, the opening of which is known to have occasioned a great outbreak of fever here. You say that you would not live in a house next it, nor at the end of the street, nor at the end of the next street; but where should you begin to live so as to be safe from the effluvia of that drain? We cannot answer that question. I suppose if I get to Oxford I am safe from that drain, but we have no chemical tests,—because that really is the only point at issue,—to apply to the air to say whether or not it contains injurious or poisonous organic matter from the drain. In the atmosphere just as in the water there are constant processes going on with great efficiency to destroy those noxious gases; and a person would argue, just as is done in the case of water, that you have sulphurous acid from the chimneys of London, you have the oxygen of the atmosphere, you have nitric acid, you have ozone in the atmosphere. All these agents, happily for us, are at work destroying those noxious gases from the drains and sewers and other places. But when is their work completely done? That is what we do not know. Another most important thing is this, that really there is no reason whatever to believe that the injurious character, either of sewage or of the gases from a drain, depends, fundamentally, upon the quantity of that sewage or of that gas, in all probability it far more depends upon the quality of the sewage, namely, what it consists of. Now what is the nature of the poisonous matter in the atmosphere or in the sewage? We do not know that at all. Therefore how can you possibly say when that poisonous matter is got rid of from the water or from the air. It is a question that with the means at our disposal it is absolutely impossible to answer; and I say, as I said before, that I think you have a much better chance of getting at these relations through accurate statistics properly applied, than you have through chemical analysis, because chemical analysis is one of the poorest things possible to reach those delicate quantities. You cannot get at those small quantities at all. Chemical analysis must be limited by our power of weighing and measuring; we can only do those two things. We can weigh and we can measure, and we can do that with a certain accuracy, and there we stop; but that accuracy is not capable of being multiplied *ad infinitum*. It may go on to a certain point, but we cannot go beyond that point. I think that it is impossible absolutely to answer those questions, for we have not the data; but the question arises, as I said before, whether a prudent person like to drink water which contains a certain quantity of nitrates and nitrites, or that when analysed is found to contain a certain quantity of organic carbon and nitrogen,—carbonate water into which you have deliberately put cartloads of sewage at some time or other in its course.

Sir B. Brodie, Bart.

25 March 1868.

7012. From the tables before us it would appear that the Thames water, when delivered into London, shows, independently of the presence of nitrates, which possibly may be ascribed to more than one source, a no larger quantity of actual organic matter than do the waters from the lake district, which come from purer and better sources?—This depends on the way in which we estimate the organic matter. However, even assuming that the ratio of the organic nitrogen to the carbon affords such a measure, it appears that the water supply of Preston from Longridge hills does not essentially differ in this respect from Thames water.

7013. But supposing that the water flowed a certain distance, whatever it may be, is there no limit beyond which you would say that the sewage would become innocuous?—General experience decides these questions for us, we do not decide them by scientific

Sir B. Brodie, Bart.

25 March 1868.

tests. We know very well that under ordinary circumstances these things do not kill people, because if so the poisonous effects of such water would have been found out long ago; but, as I said, it is not a scientific result, it is a conclusion of practical experience. I myself should never like to drink water into which sewage has deliberately been put, because I do not know when it gets out of it again. We know that it is put in, but we do not know when it gets out.

7014. Still that process of oxidisation is constantly going on in the soil and in the river, and therefore there must be some point at which the perfect destruction or oxidisation of this animal matter must take place?—What I think is much more important still is another point, namely, the great dilution of the material, and I should rely upon the dilution quite as much and more than upon the destruction of the injurious matter. Supposing the sewage of a large town such as Oxford poured into the river, there are numerous feeders and tributary streams to the river which effectually dilute the sewage. The sewage is gradually getting proportionately less and less, and therefore its noxious character diminishes and ultimately disappears.

7015. Have you paid attention to spring waters?—Not much.

7016. Have you paid attention to the action of soft water upon iron and lead pipes?—I am familiar with the usual experiments upon the subject, but the difference of action of different waters on clean lead is certainly marvellous. If you take a pure distilled water, and put into that pure distilled water a piece of clean lead, the next day the pure water will be full of lead, you will see in the water a large quantity of crystals of carbonate of lead. But if you take water containing a good many salts (for instance, sulphate of lime,) not a trace of lead can be discerned, and there is no doubt that soft water more readily acts upon lead than hard water.

7017. Have you noticed that if you expose lead to those pure waters of Wales and Cumberland, the action on the lead is exceedingly different, in some cases being very powerful, and in other cases very slight, or no action at all?—I do not think it is known quite why one water acts upon lead and another does not, for it does not appear that all salts are equally efficacious in preventing this action. But it is the bright lead that is acted upon and not the tarnished lead.

7018. Have you known any cases where soft water has been used in towns and any ill effects have arisen from it?—No, I cannot say that I have had my attention turned to that subject.

7019. Do you anticipate that by taking the waters of Wales, or the waters from the lakes in Cumberland, and bringing them to London by a given length of pipes and aqueducts, there would be any change produced in the qualities of the waters by the time they reached London, either by the action of the metals over which they passed, or by their action upon the carbonate of lime in the mortar or in the rocks used in the construction of the aqueducts?—I should really think not; but even there, of course, care would have to be paid to select the proper materials for the conduits. It would be very unlikely that the water would be to any appreciable extent contaminated in the way you mention by passing from Bala to London.

7020. Do you consider that the water would be apt to take up any of the lime, and would reach London any harder in consequence of that circumstance?—You would have to consider what the material was through which the water was conveyed. If we suppose that the water was in brick channels, the lime could only come from the mortar and other cements which were employed. I should think it very unlikely to take up much, but such a thing could be tested. You could easily ascertain on a small scale how much it would take up.

7021. (*Chairman.*) Is it not the fact that the surface of stone or metal in the aqueducts becomes coated very soon?—No doubt generally; but not in the case of soft water. I think that soft water would always have a tendency to appropriate to itself the salts of lime, but I should hardly think that that would be a source of difficulty; however, it would be very easy to try that experiment. I mean you might take a quarter of a mile of pipe, or the description of channel through which you were going to convey the water from Bala to London, and pump water backwards and forwards through it, and analyse it and see whether it had taken up any lime or not, and what quantity. That is a question which might very easily be answered.

7022. (*Mr. Prestwich.*) Have you ever resided in a district where soft water was in habitual use?—I have frequently resided in the Welsh district in question, and I know it very well indeed, but not in the towns. At Oxford, as you are aware, our water is hard.

7023. Have you any reason to suppose that the use of soft or hard water as a drinking water produces any difference of effect upon health?—I cannot say I have reason to think so.

7024. Have you reason to suppose that the health of a district is independent of that?—I have no reason to think it to be dependent upon it.

7025. Is there not a want of direct experiment upon that subject?—Oxford is a place where the spring water is extremely hard, and injuriously hard for every purpose, but I never heard that it had been made out that Oxford was liable to any particular class of complaint from that reason. If it were so, I think it would have been discovered; but perhaps some physician from the infirmary might tell you to the contrary.

7026. Do they not use the Thames water at Oxford?—No, they do not use the Thames water now at all. They get it from a reservoir supplied, I believe, by surface drainage.

7027. Do you know the degree of hardness of that water?—No, I do not. I was speaking of the well water when I said that it was so very hard. The town supply is not so hard as the well water, but I have been in the habit of using well water.

7028. (*Colonel Harness.*) You have stated that it is very difficult to detect small quantities in the analysis either of the atmosphere or of water; how small a quantity of unconverted sewage could you discover to be contained in a given quantity of water?—I should not like to answer that question, because I should like to try that experiment for myself; but Dr. Frankland says that one part of sewage in 1,000 of water may be detected.

7029. Would it be a large proportion of the water?—It would be very difficult to detect a minute proportion of sewage, but what I meant to say was that, nevertheless, these minute proportions may be, although not necessarily, extremely injurious to health; and my reason for saying that is this, that we know that in the atmosphere minute proportions of organic matter which we cannot detect by any chemical agency, do set up and continue most important chemical changes, and so it is a perfectly possible and conceivable thing that a very minute proportion indeed of sewage in the water might be most extremely injurious to health. I say that partly from general experience, and partly because I have had occasion myself very frequently to observe the vast importance in chemical changes of what people so frequently pass by as inappreciable quantities of matter. Indeed, I have occasion to see more and more every day that minute portions of matter, which previously were not suspected at all to exist, exercise important influences on chemical transformations.

7030. In reporting upon a water which contains sewage, I presume you would not say that it contains so much sewage, but that it contains such and such ingredients which may or may not have formed part of sewage?—Yes, that is all, I should say, and that is obviously all that can be said. It may contain no injurious matter at all, or it may possibly be that the very little that has escaped destruction is injurious

matter—we are very much in the dark upon that subject.

7031. Then it might contain a considerable quantity of sewage without its being in the power of a chemist to say this thing or that thing is sewage?—He might say with very great probability, that it once had been organic matter. I think that the method which has been proposed by Mr. Wanklyn for the analysis of water, which is mentioned in the evidence before this Commission, may be available, perhaps, for the detection of small quantities of organic matter in the water, although I do not see how it can be used for the quantitative estimation of that organic matter.

7032. Was your attention drawn to the part of Dr. Frankland's evidence in which he alludes to having mixed a certain quantity of choleraic matter with water which he was examining?—Yes.

7033. What effect had that evidence upon your judgment?—It confirms what I said, namely, that you may have very minute portions of organic matter in the water which may be very deleterious indeed, and which, nevertheless, you cannot detect.

7034. Would you call the $\frac{1}{10000}$th part a very small proportion?—I should call it not a very small proportion, it is quite an appreciable and a real proportion.

7035. If water could contain the $\frac{1}{10000}$th part of foul matter, and you could not rely upon chemical tests for its detection, you would not call it a good drinking water?—Certainly not; that is just what I wished to observe.

7036. Has your attention been drawn to the analysis of sewage water which has been used for irrigation, and after passing through the soil has been returned to the river?—I have said all I have to say on that point.

7037. Referring to the analyses before the Commissioners, is the water, after being used for irrigation, very much better than the original sewage?—There is a good deal of alteration in the character of the water after passing through the soil—what is termed organic carbon in the one case, you see, is 1·104, and in the other it is 5·888, and the nitrates seem to be the same. I think the best test of the power of the chemist in this respect would be to put a number of analyses before a chemist who is possessed of full information on the subject, and let him from the analyses, without knowing whether sewage has been put into the water, say whether sewage had been put into the water, and how much. When he could do that with certainty, then you would be sure that he had discovered a method of determining the sewage. Do not tell him what the water is from which the analyses are made, but send him, say 100 analyses, and let him form his judgment from them.

7038. (*Chairman.*) Supposing he were to misread the result of his own analysis and to attribute to the presence of sewage that which might be attributable to some other cause, what would you say?—It is just the same whether he made the analysis himself, or another person made it; assuming the analysis to be accurate.

7039. (*Mr. Prestwich.*) What course do you consider the most efficacious one to get rid of sewage contamination from the towns on the river?—The best is not to put the sewage with the river at all, that is the best answer I can give, and indeed, that is really the only course by which you can be certain that you have not got it in. I certainly do think it a very good thing to employ the processes used for the filtration and destruction of sewage, and they are *pro tanto* beneficial. They really help the matter a good deal, but I do not think that they are entirely effectual. There is no known process that I am aware of for, on a large scale, destroying the injurious qualities of sewage.

7040. (*Col. Harness.*) By throwing it upon the land you absolutely get rid of a large portion of the sewage, and what is left is somewhat improved?—Very greatly improved, but I should not like to take a glass of water and drink it from just the spot where it went into the river, still less to make it one's daily and habitual beverage.

7041. (*Mr. Prestwich.*) If water is supplied to a town from a river which in a part of its course has received previous sewage contamination, and if that water is used on a large scale by that town and produces no ill results, and chemical analysis fails to detect anything unusual in its character, is it not a fair presumption that such water is wholesome and good water for the use of a town supply?—If it be used without injury to the inhabitants, really chemical analysis is altogether superfluous. But the question is whether it can be always and permanently so used. That seems to me to be the real point at issue. We should have found out long ago the injurious effects even of small quantities of sewage if the sewage were always injurious; but that is not asserted. It is only supposed that, under certain exceptional conditions, even sewage may become very injurious. The injurious character of a water impregnated with sewage matter might not be discovered for years. You might long go on using it, for years, and it might not be discovered, and yet you might have some outbreak of disease in the place which, nevertheless, might be connected with the use of that sewage water.

7042. (*Chairman.*) Then, under ordinary conditions, although you could not detect in the health of the inhabitants any injurious effect from the water, still if there are in the atmosphere increased causes of zymotic disease, the drinking of that water might ripen those causes to serious effect?—I can understand that, under certain conditions, the water which was uninjurious at one time might become injurious to the inhabitants; but what I was thinking of was, that the water, without being always poisonous, or always containing anything even detrimental might, under certain exceptional conditions, contain matter which would be very detrimental, and this might only occur now and then just as it is supposed to have been the case in the outbreak of cholera in the east of London. Of course the water in London must have been contaminated over and over again with sewage without cholera ensuing. I believe it has been mentioned in the evidence here that water becomes contaminated from broken sewage pipes; how many broken sewage pipes have there been in London during the last 10 years?

7043. (*Mr. Prestwich.*) You consider then that with regard to the effect of water upon the health of the inhabitants, it is rather a question for the medical observer than for chemical analysis?—I really think so. I think that chemical analysis is not yet sufficiently advanced (whether it ever will be I do not know) to pronounce a decision upon the matter, and that you have a better chance of getting at the real connexion between the injurious matters in the water and diseases generated by those matters through statistical observations carried on upon a large scale than through chemical analysis. Statistics elicit relations of cause and effect on which you cannot deliberately experiment. You cannot poison people for the sake of trying the quality of water.

7044. (*Mr. Harrison*). Taking into consideration that London now is supplied from the Thames, and assuming the water to be well filtered, are you prepared to say that there has been any positive injurious effect from the Thames water produced upon the general health of London?—No, I certainly am not prepared to say that from my own personal knowledge and experience, but I do not know the facts sufficiently to pronounce an opinion one way or the other; it would require a very considerable examination of the evidence to enable me to do so. This is a question for physicians.

The witness withdrew.

W. A. Miller, Esq., M.D.

5 March 1868.

WILLIAM ALLEN MILLER, Esq., M.D., examined.

7045. (*Chairman.*) You are, as we all know, professor of chemistry in King's College?—Yes.

7046. Have you directed your attention for some time to the quality of the water of the several companies supplying the metropolis?—I have had occasion to do so for many years past.

7047. Have you formed any decided opinion as to the value of soft water, as compared with hard water for domestic purposes?—There is no doubt that soft water, for all purposes excepting for dietetic purposes, is preferable to hard.

7048. Or for purposes of manufacture?—For purposes of manufacture and for cleansing and ordinary domestic use it is preferable.

7049. Are you of opinion that the use of soft water would be a great saving in soap to the inhabitants generally for cleansing purposes?—There would be a certain saving, but I think that the amount of saving has been somewhat exaggerated in some estimates which have been made regarding it.

7050. You have seen the evidence upon that point which has been laid before this Commission, do you concur in that view?—Some years ago I was a member of a Commission for the purpose of examining into the supply of water to the metropolis, and we very carefully examined into that question of economy in the use of soap. With regard to the portion of soap which is destroyed, one degree of hardness may be reckoned to destroy about 10 grains of soap per gallon, that is, supposing that the whole of that degree of hardness is expended in decomposing the soap. At that time, in 1851, that was the general conclusion at which we arrived.

7051. That was a Commission composed, was it not, of yourself, Professor Graham, and Professor Hofmann?—Yes.

7052. No doubt, although you may not concur in the precise quantity alleged to be saved in the consumption of soap by the use of soft water compared with hard, speaking generally there would be a considerable saving by the use of one over the other?—Undoubtedly.

7053. And probably the use of soft water for cleansing purposes would be beneficial to health?—Undoubtedly it is far more agreeable, as everybody knows, to use soft water than hard.

7054. Then as to the effect of soft water as compared with hard water on the health, apart from cleansing purposes, would the use of soft water promote the health of the inhabitants to a greater degree than the use of hard water?—Any precise observations are difficult to obtain, but I think, so far as observation goes, it is a matter of indifference whether it is hard or soft water.

7055. When you use the term "hard," you mean, of course, an ordinary and not an extreme degree of hardness?—Yes.

7056. Would 10 degrees of hardness in your judgment be injurious?—Not merely as hardness; it depends upon the quality of the hardness. Chalk waters, I consider, are waters which are perfectly wholesome, but waters which have a similar degree of hardness from sulphate of lime there appears to be some reason to believe are found occasionally to disagree with persons. Still there are waters which are supplied to large populations containing sulphate of lime, and very hard sulphate of lime waters. For instance, the population of Wolverhampton and Birmingham are supplied with water of this kind. It is certainly objectionable, but what I was going to say was that the evidence in that case is that there is no sensible injury to health directly traceable to the water as far as as observations go. I believe, generally speaking, the impression is that the hardness caused by sulphates of lime and magnesia is more likely to produce certain slight derangements than the use of chalk waters of a similar degree of hardness.

7057. You would have no doubt that water of something like 15 to 20 degrees of hardness might be used for domestic purposes?—I should not think there was the slightest reason to suppose that any injury would result from such water.

7058. Then you attach no value for drinking purposes to soft water over hard?—From long habit I should certainly prefer hard water for drinking purposes to soft water.

7059. With regard to the condition of the water from the Welsh and the lake districts when discoloured by peaty matter, could that peaty matter be removed by exposing a larger surface to the action of the atmosphere, and bleaching it, or would it be precipitated; and secondly, if still present in the water, would it act injuriously upon the human system?—I believe that it has no injurious effect upon the system, and it also is partially deposited in the storage reservoirs—it becomes oxidised and rendered insoluble.

7060. When conveyed through a culvert from either the one district or the other, in the course of its passage to London a large portion of the colouring matter would be destroyed, would it not?—That would very much depend upon whether it was an open or a closed culvert.

7061. It would be partially closed and partially covered?—I have no special facts upon that point; that is a question for engineering observation, I think.

7062. With regard to the presence of sewage in water you have heard the questions which have been put to Sir Benjamin Brodie, are you of opinion that, supposing sewage contamination to exist in water at point A and the water to travel from there to point B, a distance of from five to seven miles, that the sewage contamination would be destroyed, that the oxidisation will go on and break up the original elements of the sewage, and that it would not then be present, or that if present it would not be injurious to health?—I know that it is partially destroyed, but I cannot say what distance would be necessary to destroy it. I have no observations to enable me to say, nor do I think it would be an easy thing to devise any accurate observation which would prove it.

7063. You have examined the water of the Thames, I believe, frequently?—Yes, very frequently; one summer I was examining it every week.

7064. Did you, in the several analyses which you made, detect the presence of sewage?—Yes, very largely. At that time, the body of stream water in the Thames was exceedingly scanty; the sewage oscillated backwards and forwards, and formed a sort of black inky liquid, and with each turn of the tide it kept oscillating backwards and forwards in a short distance.

7065. You are now speaking, are you not, of that part of the river which is subject to tidal influence?—Yes.

7066. What was the state of the water at that part of the river above Teddington lock where the water companies are now taking their supply?—Above Teddington lock the water was very good, even at that time when there was but a scanty supply of water in the river.

7067. What year do you refer to?—I am now referring to the year 1859.

7068. Did you detect in the water taken from above Teddington lock the presence of sewage?—There was organic matter, but I should not have called it sewage.

7069. Did you then form an opinion that it was traceable to sewage or partially traceable to sewage or to some other cause?—I did not specially determine whether it was sewage matter or what the origin of the organic matter was.

7070. Would there be a difficulty in determining whether the nitrates were due to one source or partly to one source and partly to another; for instance, the drainage of land, the manuring of farms upon the watershed, and the washing of the remains of the sewage into the river?—I do not think there is any means of determining what proportion of the nitrates

is due to the natural supply from the chalk springs, and what is due to the oxidised sewage. In fact there is no means of determining that. They exist exactly in the same condition in the water, and therefore a proportion of the nitrates may be due partially to the one cause and partially to the other, the proportions varying with accidental circumstances.

7071. Although you have made no special experiments as to the effect of the action of the atmosphere upon sewage mixed with a large body of water and travelling in a stream four or five miles, have you from general observation arrived at the conclusion that the condition of water for human consumption is very much better at point B than at point A higher up?—There is no question about it.

7072. You have seen the evidence of Dr. Frankland in which he refers to the presence of sewage in the form of skeleton; if the view which he takes is a correct one would the presence of that skeleton be injurious to health do you think?—I understand that merely as a figurative expression showing the existence of nitrates and ammonia in the water. Neither of those things in themselves in small quantities is in the least degree injurious. I am speaking now simply of them after they have been completely converted into that condition of nitrates or of ammonia.

7073. And you are of opinion that in that condition they would not be injurious?—They would not have any injurious effect, always supposing they exist in small proportions such as they appear to have been found in the analyses.

7074. You are aware Dr. Frankland takes a very strong view of the presence of that skeleton of sewage, because, in referring to certain wells used by the Kent waterworks company, where the water is pumped from a depth of 250 feet through the chalk, notwithstanding the filtration at that depth he still detects the presence of those skeletons of sewage?—That is to say, he finds nitric acid or nitrates, and he assumes what I think he is not justified in assuming, namely, that those nitrates are the result of the putrefaction, or rather of the decomposition of sewage matter. No doubt they are formed by that operation in a great number of cases, but to say that they are always formed so would be, I think, far beyond what the facts warrant.

7075. Supposing you found in a river in its ordinary course a quantity of nitrates and nitrites, do you think that if the water were filtered through gravel and through chalk a depth of 250 feet it would be possible still to find the presence of a form of sewage?—I object to the expression "a form of sewage." I should not say that it was a form of sewage. I should say that it is the result of the oxidation of substances containing nitrogen.

7076. But, using the language of a chemist, Dr. Frankland calls it a skeleton; that means a form at all events of some pre-existing body that is found in a certain condition?—I do not take it as a form of any pre-existing body; it might be due to a substance which is actually there, and as actually there it does not indicate danger to those who use that water.

7077. Nor would it point to its original condition as being a part of sewage?—Certainly not. I do not deny or doubt that in a great number of cases the presence of nitrates does indicate the previous existence of some organic contamination. The only difference between Dr. Frankland's view and mine is this, that he assumes, apparently in all cases, at least if I read his evidence aright, that nitrates invariably point to previous sewage contamination. I think that that is not justified by other observations. The experiments of M. Boussingault and others show distinctly that the formation of nitrates does occur where there can be no suspicion of previous sewage contamination.

7078. Supposing the sewage were applied to land in irrigation, what effect would that have upon the water which ultimately finds its way to the river?—I do not know that upon my own knowledge, I know it merely upon the reports of others; but according to those reports the water is very materially improved by the operation, the diminution in the quantity of organic matter is very considerable.

7079. You have not tested the water at Croydon, after the sewage has been used for irrigation?—No, I have not.

7080. Therefore you are unable to say whether the water so discharged is or is not injurious to health, although it may pass off in a clear condition?—Clearness is not by any means a proof that the water is wholesome.

7081. Taking the sources of supply suggested to this Commission, either from Wales or from the lakes, as compared with the source of supply to the metropolis at this moment, to which would you give the preference?—Certainly, looking at the thing merely from a speculative point of view, one would prefer a water which had not received previous sewage contamination.

7082. Are you of opinion that water once contaminated with sewage can never be considered a safe water afterwards?—I think experience is quite against that. I think it is safe; evidence shows that it is safe in the majority of instances. There may be cases in which danger is produced.

7083. (*Sir B. Phillips.*) You have had no experience of any danger having arisen from the use of such water?—I am not myself practising as a medical man, therefore I can only speak from the reports of others upon that subject.

7084. Have you lived in London all your life?—I have lived in London for the last 30 years nearly.

7085. (*Chairman.*) Have you formed any idea as to the effect on the health of the present intermittent system, as compared with a constant supply, having regard to the means of storing water which, as you are aware, in the metropolis, especially amongst the poor, are very imperfect, namely, in ill-constructed vessels, the water remaining in a position in which it is absorbing gases from privies and other places, and having regard to the fact that a constant supply would get rid of that means of storing?—Looking at it entirely from an abstract point of view there can be no question that a constant supply is a much more wholesome method of supply than an intermittent one, on account of the manner in which the filth accumulates in those receptacles, so that although the water may have been delivered good originally, yet, from the mode of storage, it may have become contaminated or putrid.

7086. Would not a certain portion of the gases generated in a privy be absorbed in the water that is stored immediately contiguous to it?—They are liable to become so if the surface of the cistern is exposed, or if the waste pipe communicating with the drain is untrapped.

7087. Would soft water have greater power of absorption than hard?—That appears to be the case.

7088. (*Mr. Prestwich.*) Have you made any experiments upon the power of water, in a given course, to oxidise organic matter?—I ascertained a remarkable result in the course of the summer of 1859 upon the river. I took specimens of the water at Kingston, at Hammersmith, at Somerset House, at Greenwich, at Woolwich, and at Erith on the same day, and I examined the quantity of oxygen which the water contained at all those different points. I found that the quantity of oxygen at Kingston was the ordinary or normal proportion; at Somerset House it was much diminished; at Greenwich the whole of the oxygen had disappeared; at Woolwich it was much in the same condition, and at Erith the water was very much improved, showing that this diminution of oxygen had been produced by its action upon the water contaminated with the sewage of the London district, and that as it passed lower down the oxygen was again absorbed from the air, and again it became diluted with a large volume of water from below, from other sources, the Lea, the Ravensbourne, and other tributaries, and in this manner the water had again become oxidised. I look upon this as a direct proof of the effect of

W. A. Miller, Esq., M.D.

25 March 1868.

oxygen in destroying those organic contaminations which are thrown into the river?

7089. That is a case where the large addition of sewage which the river received as it passed through London, consumed all the oxygen which existed above London; but have you made the reverse experiments of the removal of organic matter by the action of oxygen?—Indirect experiments, but no direct ones—at least what I imagine is the result of oxidisation—but those experiments were brought before me; they were not experiments designed by myself. The chief experiment to which I refer was a particular mode in which water was filtered through an oxide of iron filter, which, I believe, acts as a conveyer of oxygen from the air to the water. That was in the case of the water supplied to Wakefield. The water was taken mainly from the river Calder, which flows past the town, and which is in a very filthy condition. At the time that I received it, it contained a considerable quantity of organic matter and a considerable quantity of sulphide of iron in a state of suspension, but it contained no oxygen. This water was pumped and filtered through a filter, one part of which consisted of oxide of iron, and the water as delivered in the town was one more free from organic matter than any river water which I have had an opportunity of examining, although previously it was very largely contaminated with sewage matter.

7090. Would that act for a length of time?—I have never myself had an opportunity of examining that filter, but there was an account of it given before the Commission on the Pollution of Rivers, in which it is stated that it has been in operation now for some years, and still appears to act, but it is necessary that it should be alternately exposed to the action of the air, so as to re-oxidize the iron, and again that it should allow the water to filter through it. The exposure to air, however, that is required appears to be not very long.

7091. You stated that there was no danger to be apprehended from the presence of peaty matter in waters from a soft water district; do you anticipate that there would be any indirect injurious effect produced upon the water by the removal during its flow from a distant source to London of any portion of air which the waters contained by oxidizing the peat?—If it is in an open culvert the exposure to air would, I should say, quite supply that which would be removed by the action of oxygen upon the peaty matter. If it was in a closed pipe it might be a question whether that would be so.

7092. Do you consider that the condition of water, as far as aeration goes, is a very important one for the supply of towns?—Yes, very much so. Generally speaking, a good deal may be judged from the proportion of oxygen. If the proportion of oxygen is much below the natural quantity, it is obvious that there must have been something at work to reduce it in the water itself.

7093. Do you anticipate that there would be any difference on that score with respect to soft or moderately hard waters; that is to say, if London were supplied with a water of a moderate degree of hardness, derived from sources near London, or if it were supplied with soft water brought from a distance, do you suppose that there would be any cause in operation to produce too low a degree of aeration in the soft water?—I do not anticipate that. I do not think that that would have any very material effect, but that is really a question upon which I can scarcely give an opinion which would be worth much.

7094. In looking for water for drinking purposes, what should you consider the essential or the more important conditions?—That it should be free from organic contamination to any marked extent, and clear and bright and cool, and not excessively hard

7095. Are not a very large proportion of the waters consumed in this country, or in any other country, flowing as they do over calcareous formations principally, hard waters?—Yes, they are.

7096. And the proportion of soft water used is comparatively small?—The Scotch waters are many of them very soft, and some of the waters in Cumberland are soft. Whitehaven and several large towns are supplied with soft water now, but in the south of the island the water supply is generally hard.

7097. Have you had occasion to notice whether the change from one water to the other produces any ill effects upon the health of the inhabitants?—I have no observations upon that point.

7098. You state that a certain proportion of nitrates is not injurious in water, and farther, you consider that it is not possible to say whether those nitrates are derived from previous sewage contamination or from original sources, such as springs, which are perfectly free from previous sewage contamination, as the nitrates are found in both descriptions of water?—Yes, that is the case.

7099. You consider, do you not, that in small quantities the presence of such nitrates would be innocuous?—Yes; the presence of large proportions of nitrates would no doubt indicate communication with some source of animal refuse. Well waters in towns very commonly contain large quantities of nitrates, especially in the neighbourhood of graveyards.

7100. But they contain very unusual quantities?—Yes, quite large quantities; sometimes I have seen as much as 20 grains in a gallon.

7101. Have you had occasion to analyse any waters which you have reason to believe are removed from the possibility of previous sewage contamination, and yet found nitrates present in them?—Yes, the waters from Watford, which come from chalk wells, where there can be no suspicion of previous sewage contamination, always contain nitrates.

7102. Have you had occasion to examine any springs or other sources of water supply?—I have examined a good many waters from various parts of the kingdom at different times, but the waters which I have had to examine, generally speaking, have been detached specimens of water which have been suspected of some injurious contamination, and they have been sent up in consequence of that circumstance. I have examined waters for the medical department of the Privy Council, and have done so for some years, and have had specimens from various parts of the kingdom where the water has been supposed to be injurious to health.

7103. You consider, then, that the presence of nitrates may be referred to various causes other than the existence of ordinary sewage in the water?—Yes.

7104. Organic nitrogen, I presume, is the substance the presence of which in any excessive quantity is to be avoided?—The presence of organic nitrogen may be derived from substances which are quite harmless, or it may be derived from substances which are very injurious, and we have no means of distinguishing between the two. Nitrogen is always present in such combination, not as nitrates, and not as ammonia; but the presence of nitrates is always a suspicious circumstance in water, and the greater the quantity of nitrates the more suspicious is the nature of the water and the more reluctant one would be to use such a water as a source of supply.

7105. Then are you of opinion that the mode of inquiry which has been adopted with regard to determining whether that organic nitrogen arises from animal matter or from vegetable matter fails to determine that point?—It fails to determine that point, but still, as I stated before, organic nitrogen is more often traceable to organic matter derived from animal refuse than it is to other sources; especially, for example, if a river which was known to pass through a thickly inhabited district furnished a quantity of this organic nitrogen there would be a strong suspicion that there was a quantity of undecomposed organic matter derived from animals in the stream.

7106. You have probably noticed the observations which have been made by Dr. Frankland with regard

to the suggestion which he throws out as to determining whether it can be referred to one cause or the other; do you consider that the experiments are conclusive?—I think Dr. Frankland has done more than anybody else to enable us to come to a conclusion upon that subject, but I do not think that his method at present is sufficiently tested to enable one to pronounce a very certain opinion upon it. It is a very laborious method, and I should doubt almost whether the results are adequate to the labour bestowed upon it. I have gone over with some considerable care his observations, and the method is an exceedingly ingenious one, and Dr. Frankland is a most accomplished analyst, but I agree very much with the objections which were stated by Sir Benjamin Brodie. I think the difficulties are at present that there has been no adequate verification, and that the errors of the analysis may possibly amount to as much as the substance which is to be determined. That is at present a matter under discussion. The subject is one of very great importance, and we are very much indebted to Dr. Frankland for the time and care which he has bestowed upon it, but I do not think he has settled the question as yet.

7107. Still the analyses being made by the same process would give results of the same comparative value?—Yes, they would give results of comparative value, especially in the same hands, and provided we knew what the probable error of the case was, but the probable error may amount to as much as the entire quantity which is to be determined. In some of those cases there can be no doubt that there is a very large proportion of organic nitrogen, but in cases where the quantity is small, the probable error evidently bears a much greater ratio to the amount which is observed.

7108. Can you point to any particular instance?—No, because we have not at present a sufficiently exhaustive investigation of the accuracy of the method. I think with Sir Benjamin Brodie that what is requisite is that this method, if it is at all to be relied upon, as a general method, should be most carefully and rigidly tried as to the errors of observation. Dr. Frankland has done something towards that in a paper, which he has just communicated to the Chemical Society, but I quite agree with Sir Benjamin Brodie that the proper plan is to take the same water and analyse it repeatedly, using different proportions of the water, and determining the quantities of organic matter by this method, say 30 or 40 times, so as to get the probable error.

7109. You have had occasion, no doubt, to examine the method adopted by Mr. Wanklyn?—Yes.

7110. Which method differs very materially, I believe, from that in general use?—Yes.

7111. Do you consider that there is sufficient definite value to be attached to the results obtained?—I am not able to give any opinion as to its quantitative value, but as a qualitative method I think it is of very considerable value.

7112. Do you think it a very important one for the detection of combined organic nitrogen?—Yes, it distinguishes very clearly between organic nitrogen and the nitrates, and I think that is one point in Dr. Frankland's method where further experiments seem to be needed, as distinguishing between the two.

7113. Do you not then consider this method of Mr. Wanklyn's applicable for exact analysis?—No, I do not think that at present it is made out that it is so. It appears to me that the experiments which have been made upon it both by Dr. Frankland and Mr. Wanklyn give results varying with the nature of the organic substance. Moreover, you never get the whole of the nitrogen from the organic substance, and I do not think you get a definite fraction of it. Mr. Wanklyn considers that he does, but I think that that is a point upon which he is in error.

7114. In any case you consider that it would be valuable in detecting the presence of that substance?—Yes, I think it is the best method for determining in a couple of hours whether a water is likely to be healthful or otherwise. If the water gives no organic nitrogen by Mr. Wanklyn's method, I think the probability is that the water is one which may be used. I think as a qualitative method it is an exceedingly useful one.

7115. Its value, therefore, is not so much in determining the amount of impurity, but in showing what waters are free from impurity and may be considered perfectly good waters for drinking purposes?—Yes.

7116. The method has not yet, I believe, had many months of trial?—That is so. Both those methods are at present under trial, and chemists have not yet had an opportunity of fairly testing either of them.

7117. Have you had occasion to notice the effects of soft water upon lead, and if so, what has been the conclusion at which you have arrived upon that point?—I have made a great many experiments upon that subject, and my opinion is that there is no doubt that perfectly pure water acts very rapidly upon lead. In the presence of atmospheric air and carbonic acid the action is extremely rapid, but if the water contains certain salts the action may be reduced to nothing whatever. For instance, the Loch Katrine waters act very rapidly upon both tarnished and untarnished lead in its ordinary condition. If you put a piece of lead into a bottle of Loch Katrine water and leave it exposed to the air it will gradually corrode the lead, and almost the whole of it will be converted into white lead, but that same Loch Katrine water, if it is sent through a pipe continuously, though it acts at first, will ultimately coat the inside of the pipe with a vegetable deposit which will entirely protect the pipe and there will be no action whatever upon the lead. The London waters now have always a trifling action upon lead, but it is so trifling that it is perfectly immaterial. The Loch Katrine waters, I believe, have absolutely no action after they have passed through the services for a certain time. They paint, as it were, the inside of the pipes and cisterns with a deposit of vegetable matter which combines with the oxide of lead, and so forms a closely adherent film which entirely prevents all change. I was certainly of opinion at one time that the Loch Katrine waters would be exceedingly dangerous to introduce into Glasgow, and I reported accordingly, but further examination has convinced me that that was a mistake.

7118. Have you had any opportunities of observing the same conditions in other towns supplied with soft water?—Yes, I have examined the soft water supply of several towns, at Manchester, at Whitehaven, and particularly at Inverness, and also at Perth and at Aberdeen. I visited all those towns especially with regard to the supply of soft water for the purpose of ascertaining the effect upon lead, and I did not find that there were any cases of lead poisoning which could be attributed to the use of soft water. At Whitehaven they had a hard water previously in the town, and a few years ago a very soft supply from Ennerdale Lake was introduced and there was no injury there. At first when the water was introduced they observed a few cases of injury traceable to the temporary action of the soft water upon the lead pipes, but they became shortly coated in the same way, and now I believe no case of lead poisoning is ever heard of excepting where a new lead service is put down.

7119. In your experience when visiting those various towns, had you occasion to observe the effect produced upon the health of the inhabitants by the introduction of soft water?—I made general inquiries, but I did not ascertain that there was any difference in that respect.

7120. (*Chairman.*) What time would be necessary for the formation of such a vegetable deposit upon a lead pipe as would prevent the action of the soft water upon the lead?—It depends very much upon the nature of the water, but with those peaty waters from the lakes it appears to take place pretty quickly, in a few weeks or perhaps less.

7121. (*Mr. Harrison.*) In the meanwhile, would the effect be injurious to health?—I made careful inquiries

W. A. Miller, Esq., M.D.

25 March 1868.

at that time, but I did not hear of any except half a dozen cases, perhaps, in Manchester, and one or two cases, perhaps, at Whitehaven, but still there was obviously nothing to be feared from that source of supply in its action upon the pipes generally.

7122. (*Mr. Prestwich.*) Supposing a district of chalk country were manured either by ordinary farm manure or by sewage matter, do you think it probable that rain water passing through a depth of 100, 200, or 300 feet of chalk should retain any traces of organic matter derived from any such source?—That is a question which is rather a speculative one. I should say not, but it is conceivable that fissures might occur in the chalk which would prevent the water from being thoroughly filtered, and in such a case it is possible that contamination of that kind might happen.

7123. In the absence of fissures, the tendency would be, I presume, to remove all impurities?—If it filtered through a body of chalk, it would be an exceedingly perfect mode of destroying them, because chalk is porous; it absorbs air freely, and the water is thus brought in a finely divided state into contact with the air under very favourable circumstances for oxidation. In fact chalk waters are proverbially brilliant, they are most beautiful waters when they issue from springs and perfectly colourless; if anything there is a slight bluish tinge when they are seen through a depth of 30 or 40 feet, but they are exceedingly beautiful and limpid.

7124. Have you formed any opinion yourself as to the comparative value of a supply of water of a moderate degree of hardness to a town, or of a soft water supply?—I should say that for drinking purposes a hard water is preferable, and it is liable to a less frequent change than a soft water. The principal objection which appears to me to arise in the case of soft water is that it is liable to peaty discoloration, which makes it at times very disagreeable for drinking purposes, and it is also more liable to absorb organic impurities, but as far as economical applications are concerned there is no doubt that there is economy in the use of soft water. I think that one of the principal objections to hard water is the manner in which deposits take place from it when it is used in boilers. There is always, in our chalk districts, a considerable deposit of hard adherent fur in the inside of boilers, kettles, kitchen ranges, and so on, which in time chokes the range and obstructs the passage of heat, and may occasion accidents. That seems to me to be one of the serious practical inconveniences from hard water which I do not think has been prominently touched upon.

7125. No inhabitant of London can be unacquainted with that inconvenience?—No doubt they are, and I suppose they feel the inconvenience to some extent. At the same time I should prefer, merely looking at it as an abstract question, water of a moderate degree of hardness for drinking. I must say that for domestic use soft water is preferable on account of its economy, but for dietetic purposes I think hard water has the preference.

7126. Do you know of any experiments bearing directly upon that question with regard to the effect upon health?—No, I have no observations upon that point. Having always lived in a hard water district I certainly prefer it for drinking purposes, but I believe persons who live in soft water districts are equally favourable to the use of soft water.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Thursday, 26th March 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOTT HARRISON, Esq.
Colonel HARNESS, C.B.	JOSEPH PRESTWICH, Esq.

J. Simon, Esq.

26 March 1868.

JOHN SIMON, Esq., further examined.

7127. (*Chairman.*) You are desirous of adding somewhat to your former evidence, are you not, as to the qualities of the water supplied to the metropolis?—The point on which I thought it might be desirable for the Commission to have some some further information from me, relates to a question broached in my answer No. 2838. In that answer I speak of the great power of life and death which is exercised by water companies. I have at present a fresh and important illustration of the exercise of that power, not indeed technically by a water company, but by a Local Board practically acting as such; and feeling very strongly that the public requires more protection than it yet has against the occasional malfeasances of water companies, I propose to lay before the Commission this case which turned up in our office experience in the autumn of last year. The Commission, of course, knows that our office has to inquire into outbreaks of disease. Last autumn we had to inquire into an outbreak of typhoid fever at Guildford, and I believe the shortest account that I can give of what I wish to state to the Commission is contained in a passage of my now forthcoming annual report, and if you will allow me, I will read that passage. "The epidemic of typhoid fever at "Guildford was peculiarly instructive. Guildford is "not ordinarily quite exempt from typhoid fever, and "during the first 28 days of last August, 10 such "cases had been seen scattered about in the town, "when suddenly within the next 33 days there had "arisen fully 250 cases of the disease, and of this "large number 150 had arisen within a fortnight. "The distribution of the disease especially during "the first fortnight of the epidemic, so nearly corresponded in area with a particular section of the "public water supply of the town as to raise the "strongest suspicions that this section of the water "supply was at fault; and eventually these suspicions became a certainty. First, namely, it was "shown that on one particular day in August (about "10 days before the beginning of the outbreak), 330 "of the 1,675 houses of Guildford had exceptionally "received their water from a certain high service "reservoir which had been previously filled from a "new well, and that the persons residing in or "frequenting these 330 houses constituted the part "of the population on which the epidemic influence "had almost exclusively fallen. Subsequent chemical "examination of the water of the new well, detected "in it the products of organic decomposition, and "examination of the local circumstances showed, but "too unquestionably, whence the decomposing organic "matter had been derived. The new well, no one "could doubt, was most dangerously situated in the "porous and fissured chalk stratum; it was within "10 feet of various sewers; one of which, indeed, "was traversed as a short cut by the iron delivery "pipe of the high service; and when after the "epidemic this reckless confusion of sewer and water "works was dissected, the state of things found at

" the spot was reported to us in the following terms " by Mr. Taylor, one of the Poor Law Medical " Officers of the town: ' The engineers employed " ' in the repairs of the steam engine noticed " ' some exudation on the wall of the engine house " ' next the alley where the sewer runs, and the " ' pit of the flywheel contained a notable quantity " ' of the same. As the exudation had the smell of " ' sewage, the ground was opened in the alley " ' at a point adjacent to the engine house. " ' The sewer was found leaking in various places, " ' and the soil between it and the wall of the engine " ' house was saturated with sewage, of which as much " ' appeared to run outside as inside the sewer. This " ' was found to be an old fashioned 12-inch drain con- " ' structed with red unglazed gutter tiles with butt " ' joints and common mortar. The tiles forming the " ' lower half of the cylinder were in places completely " ' worn away, and at one point several feet of them " ' were missing, and the upper tiles had fallen in upon " ' the soil below. All the joints gave exit to water, " ' and the ground was a quagmire of filth beneath and " ' on each side. Dark coloured fetid slush had to be " ' dug out and removed in baskets, making the men " ' vomit who were employed in the work.' " There finishes the quotation, and then I go on, " There, of " course, could not be any reasonable doubt but that " the passage of this filth into the well, from which " the high service reservoir was filled, had been the " cause of the epidemic. Mr. Taylor further informed " us that the whole number of deaths from fever up " to the end of the epidemic was 21, including three " or four who died in other districts after removal " from Guildford, and that he roughly computed the " total number of cases of fever from August to " December at 500."

7128. (*Sir B. Phillips.*) What is the population of Guildford?—About 8,000, I believe, but my point is that this partial outbreak of fever was caused by the water.

7129. (*Mr. Harrison.*) That water was taken from the chalk?—Yes.

7130. (*Chairman.*) But the mischief did not arise from the fact that the water was taken from the chalk but from its subsequent contamination?—Yes, from contamination at the point where the well was sunk.

7131. (*Col. Harness.*) Have you any analysis of the water as it was supplied to the population?—Yes, I have an analysis, but I am not sure that in cases of this sort much importance must be attached to the chemical analysis. The best of all analyses in such cases is the analysis of the effect produced.

7132. Its value is as a comparison?—I have an analysis, which accompanied Dr. Buchanan's report, made by Professor Miller.

7133. Is that an analysis in which you have confidence?—Perfect confidence.

7134. Will you put it in?—Yes. (*The same was delivered in, and is as follows.*)

Analysis of Guildford Water.

Four samples of water were received duly stoppered in glass bottles, and labelled as follows:—

1. Old Well, Guildford, September 26, 1867.
2. New Well, Guildford, September 26, 1867.
3. Mill Tail, Guildford, September 26, 1867.
4. Guildford New Reservoir, October 1.

In the first three samples there was an extremely scanty reddish sediment; the fourth sample was quite bright. No sensible colour, smell, or taste was exhibited in any of the samples, except that from the mill tail, which had a faint yellowish tinge and a slightly musty taste. They are chalk waters, and soften considerably on boiling; and like most chalk springs, seem to soften by exposure to the air. That from the reservoir, where it had been standing for two months, as Dr. Buchanan informs us, is considerably softer than that taken newly from the well.

There is nothing remarkable in the amount or quality of the saline matter, a little ammonia, and a small amount of nitrates are present: the ammonia derived probably from surfaced rainage, it is distinctly more in the new well water than in the old. The amount of nitrates is small in all cases. So also is the quantity of organic matter, which, however, is decidedly greater in the new than in the old well. After standing in the reservoir for some weeks, it appears, as is usual in such cases, to have undergone a partial oxidation, the quantity of nitrates having increased, whilst that of the ammonia and organic matter has distinctly diminished.

The aëration of the water from the old well is perfect, *that from the new well very defective.* But this water after it has stood in the reservoir (specimen No. 4), has nearly recovered its proper proportion of oxygen. The water from the new well, No. 2, appears to have contained some putrescible or rapidly alterable substance, which has absorbed a large quantity of the dissolved oxygen which spring water ought to contain.

I subjoin details of the analyses:—

Guildford Waters.	1 Old Well.	2 New Well.	3 Mill Tail.	4 New Reservoir.

7135. (*Chairman.*) I think when you were examined before, you were asked your opinion as to the effect of sewage contamination in rivers, and after how long a period, and at what distance of flow, the river would get rid, if at all, of that sewage contamination; have you formed any opinion upon that point?—I cannot venture to answer that question with any confidence; it is a very difficult question to answer.

7136. But are you of opinion that the water of a river which had been under the influence of such contamination would ever after be a safe water for domestic purposes?—The answer to the question, if it is to be absolutely correct, must vary with the quantity of sewage, the volume of water, and the distance between the point of contamination and the point to which the question applies.

7137. Supposing that sewage is discharged from one of the sewers, say at Windsor, would it be possible to detect the presence of that sewage seven miles lower down the river, having regard to the volume of water in the river?—I believe it would be absolutely impossible for chemists to discover it, but the practical sanitary question is different. Supposing tape worm eggs to be sent into the river with that sewage, would those tape worm eggs be alive seven miles down? Or, supposing cholera discharges to be sent into the river, or the discharges of typhoid fever, and assuming (which is a frequent pathological opinion) that the respective contagia of typhoid fever and cholera are living germs, would those germs be alive seven miles down. It is not a question whether a chemist would find out the organic matter so much as it is a question whether those particular molocules would still have their property seven miles down. I cannot say that they would not.

7138. Could you detect them at that distance?—Only by their effects.

7139. (*Sir B. Phillips.*) Might not the same disease be produced from any other cause?—The particular parasite will only come from its particular egg. You would not get hydatids except from eggs any more than you would get chickens without eggs.

7140. Are the Commission to understand you to state that it is impossible for a chemist to discover the existence of sewage at the distance named?—The possibility varies with the conditions I have stated.

7141. If it is not possible for a chemist to discover

J. Simon, Esq.
26 March 1868.

it, is it not presumptive evidence either that it does not exist, or that if it does exist it is in such minute quantities that it is in no way deleterious to human health?—I am very decidedly of opinion that that principle is not a safe one to adopt as a basis for sanitary regulations in the matter. I think the rule ought to be that no sewage should go into any water that can be used for drinking purposes. I think, even, that allowance should be made for the proper decent taste of people. Water into which sewage has been discharged is, in relation to the matter now under consideration, an experiment on the health of the population, and I do not think that that experiment ought to be tried. Moreover, as a mere matter of taste, people would rather not drink water into which sewage has been discharged, and I think that that in itself deserves consideration.

7142. (*Chairman.*) Supposing that the inhabitants of the metropolis were generally speaking in a robust and healthy condition, although they were drinking water from the Thames which had been polluted by sewage with impunity for a given period, and that the condition of the atmosphere suddenly changed and there was a general depression of the resistive force of the human system, would not the drinking of that water have a tendency to develope disease more rapidly than if they were taking water free from the objection to which you refer?—I think the drinking of such water is dangerous. It is not practicable to define the exact line at which the danger in a particular case begins. Everybody knows that water with certain obvious pollutions by sewage is fatal to health, and I do not know where to draw the line in practice between such cases and those which are practically speaking unimportant. The question whether at the sources of the Thames a particular watercloset empties into the river, may be in itself entirely unimportant to Londoners, but I cannot draw my line between that case and cases where the danger would be unquestionable; and I venture to maintain that the principle ought to be that there should be no sewage discharged into running water.

7143. Then the effect is so doubtful in your mind, that the safer course having regard to the possibility of obtaining a supply from other sources would be that water once contaminated with sewage should not be used for drinking purposes?—Yes. I would rather, however, state it in the other form, that the sewage should not be allowed to go into the water. For what can we do in London? It is all very well to say that water contaminated with sewage is unfit for drinking, and that we ought not to drink it, but when towns up the river are still draining into the Thames what can we do? We have no choice.

7144. If the Thames is freed from all discharge of sewage into it, it is quite clear, is it not, that that objection would not arise?—Quite so.

7145. And your doubt would be at an end?—Yes.

7146. Have you analysed the water from Croydon?—Not in our office.

7147. Can you give an opinion as to the condition of the water at Croydon, when it passes off?—I am not prepared to say that at present. The point with respect to which I was particularly anxious to speak was the want of public protection against such injuries as those which have been inflicted at Guildford. There, no doubt, the injury was on a small scale, but in other cases it might be on a very large scale.

7148. That is rather a question as to the *modus operandi* in the distribution of the water; it is not a question as to the source and quality of the water?—No.

The witness withdrew.

R. Hassard, Esq.

RICHARD HASSARD, Esq., further examined.

7149. (*Chairman.*) You are desirous are you not, of making some further statement, with regard to the evidence given by Mr. Bateman, in reference to the cost of your plan as compared with his?—Yes.

7150. (*Mr. Harrison.*) In the evidence which you gave on the 19th of March, you put in a table which showed the area of the drainage into Loch Katrine, and the area of Loch Katrine itself; you gave also, did you not, a similar calculation as to the area of the two divisions of Mr. Bateman's Welsh scheme?—Yes.

7151. I do not know whether you recollect my referring on a previous occasion to Bala Lake, as bearing upon that point?—No, I was not present upon that occasion.

7152. Could you give the Commission the proportion of the drainage area to the Bala Lake as compared with its surface?—Bala Lake has a surface of 1,100 acres, and the area draining towards it is 35,400 acres.

7153. Am I correct in the calculation which I have made from the previous evidence, that with regard to your Cumberland scheme, the total area of drainage is about 113,000 acres, and the water surface of the lakes 4,639 acres, or in the proportion of 1 to 25?—Yes, or thereabouts.

7154. In the case of Bala Lake, I make it to be 1 to 33, is that correct?—Nearly so, it is 1 in 32.

7155. Assuming that I am right in that comparison, that Bala Lake is 1 to 32, and your own Cumberland lake scheme is 1 to 25, a comparison has been made with Loch Katrine, which is 1 to 7?—Yes.

7156. And because the Welsh lake scheme is in the one case 1 to 25, and in the other 1 to 29, you draw the argument from that, that the exposed surface, is not sufficient to clear the water, what distinction do you draw between the Bala Lake, or the Cumberland lakes and the Welsh scheme, with respect to that?—As regards the southern portion of the Welsh scheme, I draw this distinction, that there all the waters both pure and turbid must be empounded in we same reservoir. In the lake district it is different, he there contemplate a larger area of pure reservoir as compared with their storage and their drainage. We contemplate a separation, turning the turbid water into the compensation reservoirs and using that for compensating purposes, and using the pure water only for town use.*

* The witness subsequently sent in the following additional remarks on this subject:—"I also draw this very important distinction, that as regards the Welsh scheme there is no portion of the gathering ground, except that draining into the proposed Llanwddyn reservoir, similar, as regards the clean nature of the district, and as regards freedom from cultivation, to the watershed of Bala Lake; that Bala Lake is nearly four miles in length, and that all or almost all its tributaries enter it at or near the upper end, thus giving a long period of time for the water to clear itself by subsidence and exposure. That as regards the Welsh, scheme, the very converse would be the case, as in three out of four of the proposed main reservoirs, viz., in the two reservoirs on the River Banw and in the Trefeglys Reservoir, the principal tributaries and those which would bring in the foulest water would deliver into the reservoirs near their lower or at their lowest ends, immediately adjoining the points at which the water would be drawn off for use, and that under such circumstances the dirty water would necessarily be drawn off from the reservoirs almost immediately after entering them, and the period of time available for clarification by subsidence and exposure would be extremely short, and I have stated and maintain that under these circumstances filtration could not be dispensed with, as is found to be the case at Liverpool, Dublin, and other large waterworks, where all the water, both pure and foul, is impounded in the same reservoirs, although in the cases just mentioned the main tributaries all enter at or near the upper ends of the reservoirs, and the water has consequently the utmost advantage to be obtained from lengthened exposure. In the case of Liverpool the area of water surface is to the drainage area as 1 to 21, and in the case of Dublin as 1 to 32, the last being in precisely the same ratio as at Bala Lake. In the Lake project, matters are entirely different. The drainage area is there so clean and devoid of cultivation, that only two or three of the streams (those in the lower part of the district) ever are coloured or turbid, and provision is there made for turning them, when swollen or foul, into compensation reservoirs for millowners' use, and for impounding the pure water in separate reservoirs, and using it only for town supply."

7157. (*Chairman.*) Would not that apply to the Welsh scheme also?—Certainly not; the circumstances are entirely different.

7158. (*Mr. Harrison.*) Still the comparison which you drew, the details which you give in explanation of it now, was that Loch Katrine being 1 to 7, and the Welsh scheme 1 to 25 in the one case and 1 to 29 in the other, there was not sufficient exposed area of water surface?—If you recollect, I raised my objection before that, as to the same reservoirs being used for both purposes, and I then stated that the comparison of those reservoirs with Loch Katrine was not made under similar circumstances.

7159. Do you think you are quite right in the statement that Mr. Bateman, in estimating the cost of constructing his reservoirs in the Welsh district, which is 1,060,000*l.*, has only taken in the northern portion of his scheme?—I take Mr. Bateman's own statement in his evidence of the 11th of March in answer to question 6703, where he says, "My estimate of the cost of "constructing the reservoirs which I have laid out, "and collecting all the water, upon very carefully "considered plans is 1,060,000*l.* That includes all "the flood-water courses, and the reservoirs, and all "means of collecting and storing."

7160. Taking that to be the answer, will you point out in Mr. Bateman's detail where it is that he has made that out. You say that you get it out to be 2,200,000*l.*, will you refer me to those figures?—When I gave this evidence, if you recollect, I had not gone into Mr. Bateman's detail, and I requested permission to go into it at a future day, as his evidence had been handed to me only the evening before, and therefore I had not had time to examine the estimates until the interval which has elapsed between that day and this day. In his evidence the estimate is given at question 6567, where you will find that the estimate for the northern portion is 1,089,019*l.*

7161. That includes the branch aqueduct; it is 489,882*l.* for the reservoir?—The 2,200,000*l.* which I stated that day was stated from a sum given in round numbers in Mr. Bateman's pamphlet.

7162. In his estimate the figure for the reservoirs in the first instalment is 489,882*l.*, and in the next page 570,291*l.* for the other reservoirs, which make 1,060,000*l.* as he gave it?—I included the two branch aqueducts to the Marten Mere, up to the commencement of the main aqueduct.

7163. That is not what Mr. Bateman has taken?—I take it as 2,200,000*l.* to the junction of the branch aqueducts, that is to say, at the commencement of the main aqueduct.

7164. Then you are taking a different point from what Mr. Bateman takes in his evidence?—I compared it with the similar cost of working, collection, and impounding in our estimate, that is to say, all the works that are necessary up to the commencement of the main aqueduct. I have put it in the wrong place, that is all.

7165. You have taken the two branch aqueducts, therefore Mr. Bateman's figures so far are perfectly correct?—I understood Mr. Bateman to refer to works which were necessary both for impounding and for conveying the water to the commencement of the main aqueduct.

7166. He has taken it from the point of discharge from the reservoir?—I presume that that must be the case.

7167. If you look at page 8 you will find for reservoirs and works, for collecting and storing water in the Vyrnway and Banw district, including land and contingencies, 489,882*l.*; then if you take the next page you will find this: "Second instalment of 40,000,000 "gallons additional. Reservoirs and works for collecting and storing water in the River Severn "proper district, including land and contingencies, "570,291*l.*," those are the two figures which make the 1,060,000*l.* given in the estimate?—Yes, but I take the branch aqueducts in.

7168. (*Chairman.*) Have you had an opportunity of examining Mr. Bateman's evidence, wherein he draws a contrast between your scheme and his own, and especially with regard to the cost of each?—Yes.

7169. Are you desirous of making any statement with regard to that?—Yes. I entirely object to the prices at which Mr. Bateman has estimated the cost of our project; they are very different indeed from the prices at which the Welsh project has been estimated; in some cases they amount to as much as 50 per cent. additional. I propose going into them *seriatim*, in the same way as Mr. Bateman has done. I will take, first, the relative cost of constructing the reservoirs in the two districts, and the prices at which they have been estimated. I find, by referring to our own estimates, that for the reservoirs, embankments, including puddling, pitching, and soiling the slopes, we have allowed the amount of 2*s.* per cubic yard. In Mr. Bateman's project the prices are 1*s.* 6*d.* and 1*s.* 2*d.* In one case only, viz., that of the Nant-y-Eira reservoir, which is a small one, has Mr. Bateman taken 2*s.* per cubic yard to cover these portions of his works. And as regards the cost of eduction tunnels, pipes, and valves for drawing off water from the reservoirs, in our proposed Haweswater and Thirlmere reservoirs we have taken the cost of these as 19,000*l.* and 25,000*l.* respectively, averaging 22,000*l.* for each reservoir; whilst the price that Mr. Bateman has allowed for the similar works in his scheme averages for each reservoir only 11,414*l.*, although for four out of his seven proposed reservoirs the works in the Welsh project must be quite as costly as in ours. Next, as to the cost of the land and property required for the reservoirs, conduits, and works of collection, in our estimates of the cost of the poor mountain land which would be required adjacent to Haweswater and Thirlmere Lakes, we have taken its value at 75*l.* per acre; and for the narrow stripe on the shore of Ulleswater, for the purpose of here and there constructing a new road, we have allowed 80*l.* per acre, and in addition to that we have made liberal estimates for such house property as we should require. In estimating the cost of that portion of the first section of our works from Ulleswater to the Kirkstone tunnel, the land required for which is of poor rocky quality, Mr. Bateman, in his evidence appended to his reply to question 6713, assumes its value at 100*l.* an acre. The quantity of land required is a little overstated, but that is not a matter of any very great moment. I have taken out very carefully the quantities of land which would be required for each branch of Mr. Bateman's project; and taking the areas of the reservoirs as given, and taking the width of one chain round the water's edge, to allow for beaching, fencing, and diverted roads round the reservoirs, and taking the width of the land occupied by the various flood-water courses, and by the aqueducts from the reservoirs to Marten Mere, as averaging one chain in width, I make the total quantity required for the northern section of the scheme to be 3,124 acres, and for the southern section 2,622 acres—that is, including the two branches to Marten Mere. Mr. Bateman's estimate of the cost of land required for the northern section of his project, including rebuilding a village, a church, and compensation, is 180,240*l.*, being at the rate of about 58*l.* per acre, inclusive of house property. If we deduct from the total amount of 180,240*l.* the value of the house property, estimated at the same scale which we adopt in the Lake project, that amounts to 45,100*l.*, and that will leave him available for land and compensation 135,140*l.*, or about 43*l.* per acre only, as against our 75*l.*, and as against 100*l.* at which he estimates it for us. The cost of the land for the southern portion of the Welsh scheme is taken by Mr. Bateman as 199,550*l.*, being at the rate of about 76*l.* per acre, inclusive of house property. But if we deduct from that the value of house property as above, amounting to 43,150*l.*, that will leave him available for land and compensation 156,400*l.*, or about 59*l.* per acre only. Therefore the prices that we have taken are 75*l.* and

R. Hassard, Esq.

26 March 1868.

80*l.* per acre, as against 43*l.* and 59*l.* per acre assumed in the Welsh project. We have for the earthworks 2*s.* per cubic yard, as against 1*s.* 6*d.* and 1*s.* 2*d.*, and for the eduction apparatus, tunnels, and waste weir at each reservoir we have an average of 22,000*l.*, as against 11,414*l.* in the Welsh project.

7170. Have you worked it out into a balance sheet? —Yes (*delivering in the same*).

TABLE shewing the Prices for Property and Works as adopted by Mr. Bateman in his Estimate for the Welsh Scheme, compared with the Prices for similar Matters and Works which he has adopted in his Estimate for the Lake Project.

—	Land for Reservoirs and Works of Collection, after deducting Value of House Property, per Statute Acre.	Earthworks in Reservoir Embankments, including puddling, pitching, and soiling Slopes, per Cube Yard.	Eduction Tunnel, Pipes, Valves, and other Apparatus, Average for each Reservoir.	Tunnel through Clay Slate Rock, Area 240 Square Feet, per Mile.	Tunnel and covered Conduit on Line of Main Aqueduct, per Mile.	Open Conduit on Line of Main Aqueduct, per Mile.	Syphons of Wrought-iron Pipes, on Line of Main Acqueduct, per Mile.	Observations.
			£	£	£	£	£	
Prices adopted by Mr. Bateman in estimating for the Welsh Scheme.	43*l.* to 59*l.*	1*s.* 2*d.* to 1*s.* 6*d.* in one case only, and that for a small Reservoir, 2*s.*	11,414	38,720	33,180	25,000	No wrought-iron Syphons.	
Prices adopted by Mr. Bateman in estimating for the Lake Project.	100*l.*	—*	—*	88,000	50,000	35,000	127,000	* Mr. Bateman gives no detail, but states he adopts Messrs. Hemans and Hassard's prices, although the prices at which he would have estimated these works would have been higher.

7171. (*Mr. Harrison.*) Have you any idea what the rent per acre is of the land in the Welsh district? —I have not. It is the best land in that country; the whole population is crowded into the valleys: it is the most fertile land in the country.

7172. (*Chairman.*) It is in a civilised district, because Mr. Bateman removes a church?—Yes, he removes two churches and four or five chapels. The next objection I have to raise is as to the price at which Mr. Bateman has estimated our Kirkstone tunnel. It is a long tunnel, six miles in length, out of which $4\frac{1}{4}$ miles is an ordinary shallow tunnel, and $1\frac{3}{4}$ mile is what I may term a heavy tunnel; it is in the central part of the pass, between the two working faces, where shafts could not be put The whole of that tunnel is estimated by Mr. Bateman at 88,000*l.* per mile, or 50*l.* per yard.

7173. Is it through limestone?—It is clay slate, silurian. For the central portion of the tunnel I do not think that his estimate is very much out; in fact, we have allowed 80,000*l.* ourselves for the centre portion, so that the difference is not very great between us; but I find that in the Welsh scheme, if you refer to the estimates appended to Mr. Bateman's reply to question 6567, he has taken the cost of a tunnel to carry off 120,000 cubic feet of water per minute at 22*l.* per yard, or 38,720*l.* per mile. If the water were passed through that tunnel at the enormous velocity of 500 feet per minute, or $8\frac{1}{4}$ feet per second, it would require a tunnel of 240 square feet in area, being precisely the same dimensions as that which Mr. Bateman has estimated for our Kirkstone pass tunnel. As the Welsh tunnel is through clay slate, in every respect similar to the greater portion of the Kirkstone pass tunnel, it is evident that the two ought to be estimated at the same rate of price, whereas I find in the Welsh scheme a tunnel which must have an area of 240 square feet, is estimated at 22*l.* per yard, or 38,720*l.* per mile, while for the same class and size of tunnel in Cumberland it is estimated at 88,000*l.* per mile.

7174. Is Mr. Bateman able to get more faces than you can in Kirkstone pass?—A certain portion of Kirkstone pass must be worked, of course, from two faces only, but in the remaining $4\frac{1}{4}$ miles we can get any number of shafts down that we please. I do not object to the 88,000*l.* for the central portion of the tunnel, but I object entirely to his estimate for the remainder.

7175. Can you give a short summary, showing what the difference would be?—Yes, I have handed it in. The next objection I have is as regards the covered and open aqueduct in the second division of our project, from Ambleside to Stockport. In estimating for that portion of the work Mr. Bateman takes its cost, if you refer to the estimate appended to his reply to question 6713, at 50,000*l.* per mile for the covered aqueduct and tunnel, and 35,000*l.* per mile for the open aqueduct, whilst in his own project, where he contemplates using more expensive material and a more expensive class of workmanship, he estimates the cost, if you refer to the estimate appended to his reply to question 6567, at 33,180*l.* per mile and 25,000*l.* per mile respectively. So that in our district, where we have abundant building material of every kind, and where we do not contemplate the same costly class of work as in the Welsh project, considering it unnecessary, it is estimated for us at 50,000*l.* and 35,000*l.* per mile respectively, whilst in the Welsh project the same work is put at 33,180*l.* and 25,000*l.* The facts of the case however are, that for that portion of the work, for tunnel, covered conduit and aqueduct on substructure, which is as nearly as possible the same price as the tunnelling, our estimate averages 37,360*l.* per mile, that is about 4,000*l.* more more than Mr. Bateman has adopted in his own project, as against 33,180*l.* per mile for the Welsh scheme. The open portion of the aqueduct we have estimated at 20,000*l.* per mile, which is less than what Mr. Bateman has estimated his own project at. As regards the second portion, from Macclesfield to Edgware, the works of our project, where we also contemplate a less costly class of work than that projected for the Welsh scheme, are estimated at 50,000*l.* per mile, as against 33,180*l.* for the Welsh project (that is covered aqueduct). We have estimated that portion of our work at 32,280*l.* per mile, which is very nearly the same a mount as Mr. Bateman has estimated for the same description of work in the Welsh project. For the open portion of our aqueduct we have taken 21,000*l.* per mile, and it is estimated for us by Mr. Bateman at 35,000*l.* The estimate for similar work in the Welsh scheme is 25,000*l.* per mile. The remaining objection which I have, is as to the cost at which the proposed wrought iron syphons are estimated. The pressure under which the pipes will work and the weight of the pipes I make considerably less than Mr. Bateman has done, there is a very small proportion of the total length of the pipes which will be under a pressure greater than 200 feet, and the average pressure will be somewhere about 150 feet, and the average weight per yard of the pipes will not be more than 19 cwt. We have estimated these pipes at the rate of 33,000*l.* per mile of

R. Hassard, Esq.
26 March 1868.

single pipe, which is equal to 18*l.* 15*s.* per lineal yard, and the way in which that estimate was as made up was as follows. Wrought iron, 19 cwt. at 16*s.* per cwt., that amounts to 15*l.* 4*s.* Rendering of the internal surface of the pipe with Portland cement, eight square yards at 2*s.* 3*d.*, that is 18*s.* Excavation and refilling 16 yards at 1*s.* 6*d.* that is 1*l.* 4*s.*, and the lead and labour at the joints 13*s.*, making 17*l.* 19*s.* Then the way-leave, at six acres per mile for temporary damage, at 50*l.* per acre, amounts to about 3*s.* 6*d.* per lineal yard; that makes a total of 18*l.* 2*s.* 6*d.* Then I add to that for contingencies 12*s.* 6*d.*, making 18*l.* 15*s.* altogether per yard forward. I have not any further observations to make upon the estimates, but I may mention that since I was last examined I took an opportunity of ascertaining the height of the Maiden Lane reservoir of the New River Company, and it is, as Mr. Bateman stated, 231 feet 6 inches above Ordnance datum.

7176. Then you would be unable to deliver into that reservoir?—That reservoir would require to be altered.

7177. What height?—It would require to be altered probably 20 feet, and the upper tier, if I may so term it, of houses that were served by that reservoir, would have to be put in connexion with the reservoir immediately above.

7178. Would the water have to be lifted by a stand pipe?—No, there are several reservoirs at higher levels than that belonging to the New River Company, and it could be done merely by the transfer of a few of those houses from the service of that reservoir to that of the one next immediately above it.

7179. Then do you still adhere to your previous estimate?—Certainly. I may mention that if there is any doubt, or any question raised as to the sufficiency of the fall of our aqueduct, and the height at which we propose to deliver in London, there is another mode of collecting and drawing off the water from the lake district, which would obviate all those objections, without any additional cost whatever.

7180. Would the form of your culvert resist any greater fall than you have given to it?—We propose to work at a velocity varying between 106 feet per minute and 128 feet per minute. A greater velocity than 128 feet per minute in an aqueduct of that kind I should not venture upon under any circumstances. In the open aqueduct, where the culvert has a fall of only 4 inches per mile, the velocity varies from 106 to 109 feet per minute, and where it has a fall of 6 inches per mile it is from 127 to 128 feet.

7181. Mr. Bateman's velocity is much greater than yours?—Yes, in one portion of the works, in the covered aqueduct.

7182. Would it be necessary for Mr. Bateman to increase the cost of that portion of his work?—I would rather Mr. Bateman answered that question himself. I should not venture to work at such a velocity in a covered aqueduct of that nature; 170 feet per minute, I think, was the velocity that he gave.

The witness withdrew.

Adjourned to Thursday next, at 12 o'clock.

Thursday, 2nd April 1868.

PRESENT:

SIR JOHN THWAITES IN THE CHAIR.

Alderman Sir BENJAMIN PHILLIPS.	THOMAS ELLIOT HARRISON, Esq.
Colonel HARNESS.	JOSEPH PRESTWICH, Esq.

Dr. ROBERT ANGUS SMITH examined.

Dr. R. A. Smith.
2 April 1868.

7183. (*Chairman.*) What office do you hold?—I am inspector of alkali works for the Government, under the Board of Trade.

7184. Have you directed your attention to the quality of waters supplied for domestic purposes?—Yes, I have.

7185. Have you made any analyses which you can refer to as giving information on that point?—I have made a great many analyses, but I have not brought any with me. I only intended to speak here on general principles, and especially about the organic matter which seems to have raised a discussion of more importance than, I think, any other subject in connexion with water.

7186. Will you be good enough to state your views upon the subject?—Some time ago, in studying the organic matter of water, I divided it into many parts. It had been common in analyses of water to write down the organic matter as if it had some special quality. Afterwards, however, I found it necessary to consider organic matter as a very complex substance, and instead of putting it down under one head I have put it down under at least eight heads, and some of those heads have subdivisions. The first head which I think it would be worth attending to is organic matter, which is putrefied. This would include the gases and vapours arising from putrefaction, and this is the thing which strikes one more especially on coming in contact with water which is impure; for example, in drinking it would be offensive to the smell, and generally it will give those characteristics that were found in the Thames some two or three years ago. I examine this part by means of permanganate of potash. It is very readily done.

7187. As I understand it, although you break up that which is usually designated organic matter into eight parts, still those eight parts form but one matter that is called organic?—It is so; it is one of the great divisions.

7188. None of those eight parts would have reference to anything except the original matter which is called usually by chemists organic matter?—No; but they will be as different in their properties as, I may say, organic or inorganic matter are—so widely apart are they in quality. It is difficult for one to give exactly all the particulars, but I will first say how I examine the gases of putrefaction. I use generally permanganate of potash for that purpose; that was the plan adopted by Professor Vorckhammer, of Copenhagen, some years ago, for organic matter generally, and it has been adopted by several chemists since, and rejected by several others as of no value. I find that it is of value for some points, but it is of no value in ascertaining the whole organic matter. I have rejected it therefore for the whole organic matter, but have adopted it for the putrescent organic matter. As many opinions have been given concerning this process, I may say that I cannot wholly agree with any party. I do not know how to use it so as to ascertain the whole organic matter, but I will not say that it cannot be used so. I say, however, that the putrid matters which I estimate so as to obtain comparative amounts by the permanganate are not estimated at all by any other mode known to me, and chemists as a rule reject them entirely. They boil them away, and disregard the most dangerous and

Dr. R. A. Smith.

2 April 1868.

the most offensive substances next to germs of disease seeking to reach bodies which are doing no harm at the time, and may or may not do harm afterwards according to circumstances. In other words, the non-putrid nitrogenous matter is considered of more importance than the putrid. This may be when the water is not to be used at once, but to be stored, and when we know that the non-putrid matter in it will become either putrid or living. The permanganate results are almost entirely in agreement with those of the senses, but they are more refined. Any chemist who neglects to ascertain if nitrites, iron, and such substances are present affecting the permanganate, must bear the consequence of his negligence. I find that by examining sewage water in this manner one arrives at results which I think are of importance. As an example of that I may give a short description of an examination of the waters of the Clyde which I made in the year 1866. My object was to trace the sewage water down the Clyde from Glasgow into the ocean. I therefore took specimens at different places from 6½ miles above Glasgow almost to Liverpool, and I obtained results which I think are interesting, and also valuable. At the place where I began, which was 6½ miles above Glasgow, it appears that the oxygen per 100 gallons required to oxidise the decomposed matter was 3·15; at 5½ miles above Glasgow it had increased to 4·55, further down to 5·95, then to 15·40, and so on.

7889. Are there any sources of contamination above the point where you took the water at 6½ miles above Glasgow?—Yes, there is the small town of Hamilton, and the town of Bothwell.

7190. Do those towns drain into the river?—Yes. I may say that there are also substances in the water which originally would have affected the test; that is to say, there is peaty matter which would affect it, and that is also to be taken into consideration. However, the quantity rose up to 15·40, then 11·55, and then 10·85; then about 12 miles down it had gone to 4·55, and 18 miles down it had come to the position in which it was 6½ miles above Glasgow, that is to say, it requires 18 miles to make that progress; afterwards, where it began to go into the Frith of Clyde or the sea, it fell down to ·70, and at last I may say that ·35 was about the point at which it stayed in the ocean. I will hand in a table of those observations.

The witness delivered in the following table:—

—	Time.	Oxygen per 100 Gallons required to oxidise the decomposed Organic Matter.
	Augt. 15th, 1866.	
6½ miles above Glasgow	3.30 p.m.	3·15
5½ miles above Glasgow	3.15 p.m.	4·55

Off Wemyss Bay (low tide)	4.30 p.m.	0·875

7191. (*Mr. Prestwich.*) What quantity of water do those numbers refer to?—I made the experiment simply upon 100 cubic centimetres, that is about 1,500 grains of water, and those numbers may be taken as simply comparative. I believe this gives a fair idea of the progress of purification of sewage water as it went down the river, and it shows that a considerable time is required to complete that purification which did not occur until the Firth became four miles broad, and until the water had gone down 22 miles. I think that is an important fact.

7192. (*Chairman.*) I understand your statement to be that a sample taken 18 miles below Glasgow was found to be equal, at that distance, to a sample taken six miles above Glasgow?—Yes, in its power of dissolving oxygen, showing how little it was aerated.

7193. Do you know at all what time would be occupied by the water travelling down from Glasgow to 18 miles below?—It is a tidal river, and it would be difficult to answer that question.

7194. It would oscillate, would it not, from one point to another?—Yes, it would take a long time; there are a number of things to consider in this matter. I do not call the examination I made complete. It is the examination of only the relation of the water.

7195. That rule which you applied to the Clyde, where there is salt water, would not apply to an ordinary river not being a tidal river?—No, it would not apply in such a case; it would not be the same in a river not tidal.

7196. Have you formed any opinion as to the probable distance and the time that the water would require to purify itself, after being contaminated by sewage matter, I mean in an ordinary fresh water river?—It is rather a difficult subject, because it depends upon the size of the river, and the amount of sewage, and the peculiarities of the mud and bottom of the river. Some kinds of mud take down the organic matter much more rapidly. Altogether it is a very complicated question, and I doubt whether a rule can ever be laid down; every river would require to be examined for itself, at least for a long time to come, till we can get nearer the point. I have a few facts

which I intended to mention to the Commission about the Thames, and I may say that I have a few about canals. I know that in 16 miles of flow of a canal near Manchester, the organic matter was still sufficient to make the water appear not very agreeable, but still I could find scarcely any ammonia in it. Putrefaction had taken place, and the ammonia had nearly evaporated in the 16 miles.

7197. Have you followed out that idea with the view of ascertaining whether sewage can be detected at 18 or 20 miles from the point of discharge and pollution?—In the flowing canal to which I alluded the water had lost all its richer manurial qualities in 18 miles, but had preserved offensiveness enough to prevent it being used to drink. I may say what I found in the Thames. Above Reading very little impurity was found in the Thames, but below Reading it was very marked indeed, and it never disappeared in any part below Reading.

7198. (*Mr. Harrison.*) For what distance down?—Any part. I went down to London Bridge, and it was visible in any part below Reading.

7199. (*Chairman.*) Did you detect the presence of sewage from every sample that you took below Reading to London Bridge?—Yes, what I believe to be caused by sewage; it was organic matter, which in its decomposition showed a great deal of animalcular life, and which I believe to indicate so much organic matter of a very active kind, probably dangerous.

7200. Supposing there had been no source of contamination below Reading, would you then have been able to detect the presence of sewage in the river, because, as you are aware, down the river there are fresh sources of contamination going on?—Yes, I think there would have been a little. I may say that above Oxford I considered the water extremely pure, but below Oxford, and I might say down to Pangbourne, it was, perhaps, a little less pure, but very little. I considered at that time that it was not proper to take water from any source below Pangbourne at any rate. Perhaps I might be inclined to go higher now, but that was my view at the time when I examined the water for the Metropolitan Sanitary Commission, which is now 20 years ago nearly.

7201. Are you of opinion that a water once affected with sewage contamination is never after a safe water for domestic purposes?—I think it may be quite safe. It is so in some cases, in others not.

7202. Under what condition?—Supposing it were very impure indeed, the first thing that would occur would be putrefaction; that gives out a number of nauseous gases, and the most prominent to the senses is, perhaps, sulphuretted hydrogen. After the putrefaction had finished a great deal of the organic matter would be removed. If any remained, and it were exposed to oxidation, nitrates would be formed. Those nitrates are, I consider, so far offensive as they indicate very bad company, but in small quantities I am not aware that they can be considered hurtful. On the contrary, to some extent they are a very valuable accompaniment of organic matter. They themselves are disinfectant and prevent processes going forward which would be unpleasant.

7203. What are the dangerous associations of nitrates?—They, with some uncertain exceptions to be spoken of, indicate that organic matter containing nitrogen had been present, and ready to give out unpleasant, and, I suppose, dangerous forms of animalcular life; but when the organic matter is perfectly oxidised I suppose these forms and substances do not exist any longer. There are two modes which we know of destroying organic matter in water; one is by putrefaction. Putrefaction takes off the organic matter chiefly unoxidised. The carbon and hydrogen come off both unoxidised, and carburetted hydrogen appears and hydrogen alone. That occurs when there is very little air, but if there is a great deal of air in the water oxidation takes place, and nitrates are formed, and the organic matter is then taken off in combination with oxygen. That is the process which takes place when water is evaporated into the atmosphere and thoroughly oxidised. We may say here that the organic matter is evaporated into the large supply of oxygen contained in the water, and there it is thoroughly oxidised. The processes are entirely the same, and the destruction that takes place is accomplished by the same means, namely, oxygen, whether in the air or in the water. It may even go further. After nitrates are formed they may be taken up by the soil, because nitrates are food for plants just as ammonia is, and the very last trace of nitrogenous organic matter may be removed by plants, so that nothing whatever remains of it except those parts which were accompaniments and now are inorganic salts.

7204. Is it your opinion that after the application of sewage to the land the water filtered off and running into the river would be harmless?—If the land or the filter is not overburdened with sewage, that is to say, if no more is allowed to pass through than can be properly oxidised, then complete purification must take place. There is no water, I suppose, so free from organic matter as that which comes from deep wells. It is entirely a matter of depth, or rather, I should say, it is a matter of time, because the use of the depth is merely to keep the water in contact with the soil for a longer period. If the water is kept in contact with the subsoil for a long period without depth the same thorough oxidation must take place, but if the water is drawn rapidly through the soil the oxidation is incomplete, and only a rude filtration of the water will occur; that is to say, straining the water, which is imperfect filtration.

7205. If the earth is in a condition to filter, of course it would catch all that is in mechanical suspension, but would it equally catch all that is in solution?—Not equally, that requires considerable time. You must either have time or depth; long contact with the soil is necessary. The porous soil is the agent for transferring the oxygen.

7206. Then, as a rule, are you of opinion that it would be safe to apply sewage to land and allow the water to run off into a river which is the main source of supply to a town for domestic purposes?—It is certainly safe to apply some. I am not able at this moment to say how much. I am not able to say, considering to the new plans of irrigation proposed, that it would be proper to load the neighbourhood of a large town with sewage, and collect the water from it and use it for the town. I am inclined to think that it would not be safe; but in a thinly populated agricultural country I think we have no reason to believe that any danger can occur. In fact we may say that there is no water except of this kind to be got in any part of the country, even on the hill tops; it is simply a matter of quantity. The hills have the sewage of a very large sheep and cattle population, we may say, and that sewage is either passed under the soil or it is taken off as surface water. If it is taken off as surface water we seem to be very well satisfied with it, and the Loch Katrine water may be said to be of that class. If it is passed under the soil it is certainly very perfect, and would be probably the best that we could possibly attain; but we have no very large quantities of such in existence in the country so far as I know, so that the surface water of the hills may be said to be very dilute sewage water. I therefore conclude that it is a question of quantity, how much sewage can be put upon the land.

7207. Then you are of opinion that sewage may be safely applied to land if it is not in such a quantity as to master the filtering power of the earth in which it is placed?—I believe that to be a proper way of expressing the limit.

7208. Will you have the goodness to proceed with the statement of your views as to the action of organic matter?—Perhaps I might put it in this form: the third class of organic matter I have subdivided; two of these divisions are decomposing matter, containing nitrogen, and permanent organic matter containing nitrogen. These are the most dangerous substances, and these are estimated when the organic nitrogen

Dr. R. A. Smith.

April 1868.

is taken. Professor Frankland has made their estimation a regular part of a water analysis, and Professor Wanklyn has, by another mode, done the same. The great question seems to be what is their importance.

7209. Have you tested Professor Wanklyn's process?—I have made a few experiments with it to see if it is correct, and I am inclined to think that his experiments in principle are correct, but I have not done enough to be certain. I consider that I attain the practical end by a different method I now say that if the decomposition is such that no putrid gases are formed, we are unable to find any harm done by chemical action. Next, if the water contain substances which prevent putrefaction, as, I believe, is the case when peat is present, the amount present of organic nitrogen can do no harm. The organic body may be compared to japanned leather in comparison to putrid hides. From the first we can drink pure water, but from the second the water is offensive and dangerous. I was led to that by finding so much ammonia in the mountain waters. I find that Dr. Frankland has also found more organic nitrogen in those mountain waters, and Professor Wanklyn has found the same; but on exposing those waters to a temperature which would bring out the organic forms, that is, animalcular life, I find that the mountain waters show very little, and sometimes none. I conclude that the substances which are present in the mountain waters prevent decomposition. They are anti-putrescent, or they are disinfectant; perhaps they contain organic matter like a mummy, or perhaps in the form of leather or some such form; at any rate, we do not find that decomposition which we may call dangerous, and that decomposition which produces offensive looking animalcular life: for that reason we drink them freely and we inquire no more about it. We pay but little attention to microscopic inquiries about such waters; and we do not consider if this nitrogenised organic matter may be in a condition ready to receive and to develope organisms, or be ready to take disease by infection as it were. We cannot tell its character without examining if it is so. We must expose it to conditions favourable to the growth of the lower forms of life. If nothing appears under the microscope it is well, that is to say, it is sufficient. If something appears we must then compare the results with those obtained from pure water, and water believed to be bad. The amount of development of vital forms will not, so far as I know, correspond exactly with the amount of organic nitrogen. I think that one of the most important points to bring out. I think that experiments completely show that water may contain more organic nitrogen, and still be considered perfectly innocent and pure, that is free from hurtful impurity, such as mountain water. When we have gone so far we find our difficulty; but we must be satisfied to act upon our knowledge. I have a considerable confidence in the general facts observed by me long ago, indicating that the animalcular life increased in coming down the Thames, and that the amount of locomotion and evident vitality and flexibility in the forms were indices of the impurity or of the condition of the organic matter. We have never heard, for example, that a water containing only a few of the common diatomaceæ in the upper part of the Thames could hurt anyone. The evidence is yet to be found. In the cisterns of London the animal cular life is abundant; and as the density of the population increases the carelessness as to receptacles increases, and the microscope reveals disgusting sights. These contain organic nitrogen which is to be feared. The peaty water of it contains more nitrogen, leaves the pebbles in the lakes or rivers free from animal or vegetable life almost entirely. We cannot, therefore, compare the amounts in the two waters from the plains and from the hills. They are either not of the same kind or they are not in the same condition, that is to say, the organic matter is either not of the same kind, or it is not in the same condition; it may be less in quantity but worse in quality. In the next place I may say, if we can see nothing with the microscope and can find nothing by chemical analysis, have w any right to fear anything else? There are the germ remaining; if we can see no germs, and cannot prov that water from any one particular district or of particular class produces disease, what is it that w fear? The cattle on the hills have diseases as th cattle upon the plains, and there are numerous insect upon the hills. It must be a question of quantity tha makes us admire hill water, but not one of quality, so fa as the purely agricultural part is concerned. In othe words, we have a similar material in hill water but les of it. If the quantity is much less the hill water i taken down unfiltered, whilst the plain water is to a great extent passed through drains. The first is brown, the second purified until it is without colour. The question of quantity may be given up if the hill water is not filtered, and probably if it is filtered, but I consider that this is one of the points which requires examination. If the amount of germs is only a question of quantity they are much more likely to be removed in great quantities by the soil filtration, and by the filtration of the water companies, than by no filtration. I believe, however, that we have no right to fear that which has passed slowly through the soil. Germs, however small, seem to be retained by the soil, which takes up even smaller substances, namely, salts in solution and gases; and water from deep wells is purer even than most rainwater with us. If the germs pass into rivers we do not know how far they may be carried; on the other hand we do not know that they ever can be carried in pure water; the dissolved oxygen may destroy them, as it unquestionably does putrescent matters. A positive proof of their transmission in otherwise pure water is wanting. We might ask if a cholera germ in the water at Oxford would produce disease in London; and we might answer by asking if one cholera germ passing into the air at Woolwich would produce disease in Pimlico. This we do not know; but it seems probable that disease cannot be carried far by pure air or by water with much oxygen in it, which is equal to pure air. We are informed that the atmosphere is full of germs, but the evidence seems to be that it requires an unusual excess to attack us successfully. It seems to be a question of quantity. Still there is the sentiment remaining; we do not like that any sewage should enter the water that we drink. I am disposed to think it well to listen to this sentiment, so far as large towns are concerned, although even then we must remember distance and quantity; but so far as villages and ordinary agricultural drainage is concerned, I am not aware of any experiments showing sufficient room for fear.

7210. Is there any other point which you desire to bring before the notice of the Commission?—Yes. Another point is that the sewage from the plains is greater than that from the hills. This, then, goes against the plains, and the question simply is how much sewage will land bear. We must examine the water as mentioned to be certain. It seems to me that we must keep to actual knowledge; beyond that there may remain a sentiment, which sentiment I have strongly; but perhaps it would be difficult to induce people to spend millions upon it. After all that is said the inquiry must take place, as it seems to me, into the condition of the organic matter in the Thames waters, and especially the upper valley of the Thames, comparing the water from the hills at the same time. Until we receive that information it does not seem to me that we are in a condition to settle the question. I do not know whether I have quite explained my views. We require to examine into the condition of the organic matter containing nitrogen in the waters of the Thames, and the condition of the organic matter containing nitrogen in the hill waters, before we can give an opinion. It is not the mere amount of organic nitrogen that is of the greatest consequence, but the condition of that matter, whether it is in a state ready to putrify or give out germs of life,—vital forms. If there is neither putrefaction nor vitality I do not see how it can affect us.

7211. At present is it not the case that we have

really no positive evidence of what is called cholera germs, or the germs of any other disease?—Nothing precise. I believe it is proved that water of that kind, which we do find in many of the cisterns in the east part of London, will produce disease; and I suppose the proofs that Dr. Farr brought forward to this Commission are sound; and many other things show that the cholera was assisted into the east of London by such means as he mentioned. But in all those cases the water was visibly impure, or at least, by carefully nursing these germs of animals, they might have been seen by the microscope. I mean that so far as I understand the condition of the water of which Dr. Farr speaks, it was a water which would have produced animalcular life, although I did not examine it myself. I have, however, examined the waters in various parts of the east of London and the city; the water found in cisterns by no means resembles the water supplied by the water companies; and I could believe in any amount of disease produced by the use of such waters as were in some places seen. The forms of life which they show are very disgusting, and I believe that such forms simply show a great deal of unwholesome and dangerous matter. However, I am not a microscopist myself, although I have given a good deal of time to microscopic inquiry in connexion with water. I should be glad to see that subject examined by a microscopist.

7212. Did I correctly understand you to say that the presence of coloring matter in the peaty water had a tendency to arrest decomposition?—The presence of some matter in peaty water has that power.

7213. Does it amount to more than that; does it destroy animal life?—I am not quite sure whether it destroys animal life. I am inclined to think that it causes the organic matter to undergo decomposition in a different method. Peaty matter, for example, is always giving out ammonia; at least I have always found ammonia in the peaty water, and I suppose that this ammonia comes from the organic substances containing nitrogen, and, if so, they decompose in a manner somewhat different from that which we find in the waters of the plains. I am not quite sure as to the method.

7214. Apart from the question of cholera are you of opinion that peaty water would be injurious to health?—As a rule it is not, I think it may in some cases be so. although I have not heard of its being injurious on a very great scale. When I was at Oban last year I met Dr. Frankland, and he informed me that the water of Loch Ness was very hurtful to some persons. That rather agreed with some ideas that I had previously had that there was, in some kinds of peaty water, a substance which to say the least was not agreeable. In some peaty water there is an acid formed of a rather bitter taste; if the water is kept in a pretty close vessel for a long time the taste becomes very powerful. I tried this experiment with a specimen of the water from the upper part of the Clyde, which was very brown. I may say it was two or three years in my laboratory, and this process took a long time to go forward. The Glasgow corporation was at that time considering whether it should supply the town from the upper part of the Clyde. The acid formed in the peat is not volatile; at least the solution becomes stronger by boiling. I believe it would require a rather large amount of albumen to overcome this substance, that is to say, to decompose notwithstanding its presence. In some cases the taste is very decided in the mountain waters. It is to this that I attribute the fact which I learned from Dr. Frankland. I suppose this acid to be removed by being oxidized when in open lakes, or when it runs very far. I am not sure of that point, however, the bitter acid did not show the properties attributed to humous acids. Some peaty matter evidently falls down when it is exposed in large lakes or runs far, being rendered insoluble, perhaps, by the early stages of oxidation. I have no proof, however, that the whole of the acid is removable by the atmosphere from waters such as that of Loch Ness, in which you can taste the bitter, but I am quite sure that it is entirely removed by deep filtration. I conclude, however, that the organic substances in the mountain and the plain waters are either different or in such different company that, by comparing the quantity, we cannot draw conclusions as to their effect. I had at a former time expressed an opinion that peaty water was not hurtful. I always knew that it was not pleasant to the taste, but I did not know until lately that it might be hurtful to the stomach, causing a little diarrhœa, and for this reason I would not recommend every class of peaty water; there are great varieties. I think peaty waters might be divided into several classes after my late observations. In the water from the clay slate also there is sometimes found another substance, called chloride of calcium, which does not seem to be noticed by chemists; that also has antiseptic properties, but exists only to a small extent, although I imagine that sometimes it may be tasted in waters. Those are points which require a little examination regarding mountain waters. A great deal of the mountain water is from the surface; that from the plains has been much deeper in the ground, as a rule, and has therefore been freed from the decomposed vegetable matter and manure with which it came in contact. No water is so free from animal matter as that which passes through a great depth of soil. The soil oxidises more thoroughly than the air alone, at least more rapidly; and therefore well water is universally admired, whether hard or soft. The air in it would be found to contain from 33 to 34 per cent. of oxygen, whilst that is seldom the case in mountain waters, although in some it is very nearly as high. In the Loch Katrine water, and in some waters from Wales and Cumberland, Dr. Frankland has found it very nearly as high; but a knowledge of the amount of oxygen in the Thames water is much wanted; the rapidity of the oxidation which is going on is not at all known. If the water is found to-day to have 30 per cent. of oxygen in the air which it contains, and to-morrow to have only 12 per cent. of oxygen, or anything less than 30 per cent., it shows that oxidation is going on, and I look on that therefore to be another of the important methods by which the organic matter in water ought to be tried. I have sometimes found the oxygen in the absorbed air in the water to differ as much as from 33 and 34 down to nothing. If there is none at all it is a certain proof that the organic matter is absorbing the oxygen of the air, and there must be a great deal of impurity; if there is 33 per cent. it shows that this process is not going on, and that there is no evidence of oxidising impurity. It requires, however, to be considered whether this oxygen from the air is taken up by peaty matter or not. I believe that the peaty matters also absorb oxygen. I have examined a reservoir about 20 feet deep, containing peaty water, and I have found the upper surface of the water to contain air, having about 26 per cent. of oxygen, and the lower portion, about 20 feet deep, to contain air, having 12 per cent. of oxygen, showing I believe that the peaty water was absorbing oxygen, and purifying and decolorizing itself in that way. I do not think that there is a great deal to be feared from the peaty matter. I only mean to say that it must be more examined than hitherto, because I think most people would complain if a water, tasting like the water of Loch Ness, were introduced largely into towns, unless it could be shown that a modification of this taste were to take place during the storage or passage into the cisterns or pipes for supplying the houses. I have observed a similar taste in many other parts of Scotland and also in Cumberland.

7215. Taking the Thames in its present condition, and having regard to the recent Act of Parliament (the powers under which extend, as you probably are aware, up to and including the town of Oxford), which requires that all the towns should intercept their sewage, deodorize it, and apply it to the soil, when that arrangement is carried out and the sewage intercepted, are you of opinion that the river Thames would be a reasonable source of water supply to this metropolis, and a safe one?—

Dr. R. A. Smith.

2 April 1868.

That is an important question. I do not think that I could come to a conclusion in my own mind without a greater knowledge of the upper portion of the Thames than has yet been attained by anyone, so far as I know, and knowledge acquired in the direction which I have indicated here; but my impression is that it would be safe at some point. I do not know exactly that point. I think that the point ought to be certainly above Reading at least. Some years ago I thought of Pangbourne; but now, from the increased population, and perhaps some differences in the mode of draining the land, probably the point should be removed higher up the river.

7216. Supposing the sources of contamination were cut off, would that point then be so important?—I am considering the sewage of Oxford to be entirely separated. We should have, I suppose, then only agricultural sewage and village sewage, as there are no large towns on the Thames. My sentiment is rather against sewage, and therefore sentiment inclines me to drive the point from which the water might be taken very high up. But leaving the sentiment entirely out of view, and looking at the results obtained by chemical analysis and the microscope—I confess that I see no distinct reason which would compel us to leave the bed of the Thames for water, so far as organic matter is concerned. But the upper streams must first be examined.

7217. Having your choice, apart from the question of cost, would you elect to have the water from the Thames in preference to the water from the sources of the Severn, or from the lakes of Cumberland and Westmoreland?—When the water from the hills has none of that bitter taste of which I speak, and has none of the peaty colour, I should prefer it very much before the other water.

7218. I presume, for manufacturing purposes, you would have no hesitation in preferring a soft water?—It is very important for manufacturing purpose. I was speaking only of drinking and cooking purposes at the time.

7219. You have had a great deal of experience of the use of water for manufacturing purposes for dyeing and scouring purposes?—Yes.

7220. And you give the preference to soft water?—Yes. I have found that a very minute quantity indeed of salts producing hardness were hurtful in some dyeing processes as I considered.

7221. Have you formed any idea as to the saving of soap occasioned by the use of soft as compared with hard water?—I have adopted Dr. Playfair's calculation in that case. I have not made one for myself. I have no doubt that his is correct.

7222. Has that in your experience been confirmed?—I would perhaps not give such a high number as Dr. Playfair, but he is far in the right direction I have no doubt.

7223. (*Sir B. Phillips.*) Do I rightly understand you to say that you have examined the water in the districts at the east end of London?—Yes; I did so a long time ago.

7224. And you found them to contain decomposed and dangerous matters?—Yes; the cisterns I found very impure.

7225. Supposing that the waters, say from the lakes, were delivered into cisterns in the east of London in a perfectly pure state, would they not by contamination become decomposed and dangerous?—Yes. I know that the water that was delivered into the cisterns at the time of my examinations was infinitely purer than that which existed in the cisterns.

7226. Then it is your opinion rather that the impurity arises from the contamination when in the cistern?—Yes, from conditions connected with remaining in the cisterns. I believe that is quite certain.

7227. And not the water itself?—No; although I still think that the water is taken too low down the Thames, to say the least.

7228. (*Chairman.*) Has your attention been directed to the question of a constant as compared with an intermittent system of supply?—I have given it some attention, but I do not know that I have anything to say very peculiar upon that point except that I agree with those who believe in the great importance of a constant supply, for this very reason, that it would avoid the contamination of storing; I think that a very strong reason so far as London is concerned.

7229. (*Mr. Prestwich.*) You have been considering the waters, have you not, with reference to the organic matters present in them from the point of view of their value as drinking waters apart from the consideration of the presence of any mineral matter?—Yes, I have.

7230. I presume that you have directed your attention to that part of the subject more especially as being an important consideration with respect to health in the supply to towns?—Yes. I have a few notes regarding other substances, but they are of less importance.

7231. You have divided the organic matter in water into two heads — organic matter containing nitrogen, and organic matter without nitrogen?—Yes.

7232. Did I correctly understand you to say that it was with reference to the condition of the nitrogen in these waters that their value depended for drinking water in a town?—Yes, the condition of the organic matter containing nitrogen.

7233. I notice that in the analyses which have been made by Dr. Frankland of the waters from the Thames and the water from Loch Katrine, and from the Welsh district, and from the Cumberland district, the quantity of organic nitrogen does not vary very much in those different waters?—No.

7234. But do I understand you to state that the same value is not to be attached to organic nitrogen in the waters from the mountain districts as to water from the river Thames and so on?—That is my opinion.
